A novel NIR fluorescent probe for fast detection and imaging of methionine sulfoxide reductase A in lysosome of living cells†

Jin Gong,^{ab} Chang Liu,^a Songtao Cai,^{ab} Song He,^a Liancheng Zhao^{ab} and
Xianshun Zeng ^{*ab}

Methionine sulfoxide reductases (Msrs) play special roles in protecting proteins from oxidative damage caused by reactive species and repairing MetSO residues in proteins/peptides. However, current probes for Msrs fail to target lysosomes and exhibit a relatively slow response and short emission wavelengths (less than 580 nm). Herein, we reported a novel lysosome-targeted NIR fluorescent probe **RBSO** for fast detection and imaging Msr A by extending the linear π -conjugated system of the probe via the S_NAr^H reaction. As expected, **RBSO** exhibited high selectivity and high sensitivity for the rapid detection of Msr A in real-time via a specific Msr A-triggered methylsulfinyl reduction reaction. Importantly, **RBSO** was cell-membrane permeable and capable of specifically distributing in lysosomes, and thus detects Msr A in real-time there, providing a potential tool for monitoring Msr A activity in lysosomes of living cells.

Introduction

The methyl chains of methionine (Met) in proteins/peptides are among the most susceptible to oxidation by reactive oxygen species (hydrogen peroxide and hypochlorous acid), reactive nitrogen species and enzymes, leading to the formation of methionine sulfoxide (MetSO) residues.¹ Meanwhile methylthio groups in many drugs and natural compounds can also be oxidized to methylsulfinyl groups.² Oxidation of Met can disrupt the structure and function of proteins, and play a significant role in the development of diseases associated with oxidative damage protein accumulation, including aging-related neurodegenerative diseases (Alzheimer's and Parkinson's diseases) and cancer.³ Since Met has a chiral center at sulfur, it produces two different diastereomers, methionine-S-sulfoxide (Met-S-SO) epimer and methionine-R-sulfoxide (Met-R-SO) epimer. Methionine sulfoxide reductase (Msr), an important enzyme responsible for the reduction of free and protein-bound MetSO to Met, plays a special role in protecting proteins from oxidative damage caused by reactive species and repairing MetSO residues in proteins/peptides.⁴ Msrs have a wide range of substrate specificities and can reduce various methyl sulfoxide-containing molecules, ranging from protein-bound

MetSO residues to several small molecules, such as dimethyl sulfoxide, sulforaphane and methionine sulfoxide.⁵ Msr A and Msr B are two major isoforms of the Msr family and specifically reduce the Met-S-SO epimer and Met-R-SO epimer, respectively, and the genes for these two proteins are located within the same operon in many bacteria.⁶ The physiological electron donor for Msrs is the thioredoxin (Trx) system which, *in vitro*, can be replaced by 1,4-dithiothreitol (DTT) or 1,4-dithioerythritol (DTE).⁷ Although Msr plays an important role in the regulating a variety of cellular events, the lack of effective tools to detect their activity hinders further exploration of the enzymes under physiological or pathophysiological conditions.

In recent years, small molecule fluorescent probe technology has attracted much more attention due to its high selectivity, high sensitivity, simplicity of implementation, real-time, *in situ* detection, etc.⁸ Generally, the intramolecular charge transfer (ICT) mechanism is a versatile strategy for designing fluorescent probes.⁹ Up to now, all three reported paradigmatic fluorescent probes for monitoring Msr activity were developed by the reduction induced ICT mechanism (Scheme 1).¹⁰ However, they still bear some limitations, such as the short emission wavelengths (less than 580 nm), the slow reduction of Msr probes (30 min) and non-organelle targeting, which limit their biological imaging applications.¹⁰ The development of probes capable of detecting analytes in the near-infrared (NIR) region (> 650 nm) is particularly important for imaging applications because it can avoid auto-fluorescence interference of biological backgrounds, increase tissue penetration depth, and reduce photodamage to living samples.¹¹ In addition, there are few reports on the

Scheme 1 Structures of the Msr A probe.

distribution of Msr A in cells, and opinions about its distribution are diverse. Vouquier *et al.* believed that Msr A was located in the mitochondria and cytoplasm by purifying the rat liver.¹² Gladyshev's group found that Msr A was mainly distributed in the cytoplasm.¹³ Therefore, the design and development of organelle-targeted NIR fluorescent probes for real-time monitoring Msrs activity *in vivo* is important for exploring enzyme production and transfer processes.

Moskovitz's group has shown that mammalian Msr A has high enzymatic activity against *p*-tolylmethyl sulfoxide *in vitro*, while the substitution of methyl with the phenyl group completely suppresses the catalytic activity, probably due to the excessive steric hindrance of the substrate.¹⁴ In addition, our group has revealed that rectilinearly extended π -conjugate of the rhodamine scaffold by engaging a unique intramolecular nucleophilic substitution of aromatic hydrogen (S_NAr^H) strategy effectively enlarged the emission wavelength.¹⁵ Herein, we reported a novel lysosome-targeted NIR fluorescent probe **RBSO** for fast detection and imaging Msr A by extending the linear π -conjugated system of the probe *via* the S_NAr^H reaction. As expected, **RBSO** exhibited high selectivity and high sensitivity for the rapid detection of Msr A in real-time *via* a specific Msr A-triggered methylsulfinyl reduction reaction. Importantly, **RBSO** was cell-membrane permeable and capable of specifically distributing in lysosomes, and thus detects Msr A in real-time there, providing a potential tool for monitoring Msr A activity in lysosomes of living cells.

Results and discussion

Molecular synthesis

Probe **RBSO** was synthesized according to the procedures in Scheme 2. As shown in Scheme 2, the key intermediate **RB** was synthesized starting from 4-bromo-1-fluoro-2-nitrobenzene and

Scheme 2 Synthesis of **RBSO**. Reagents and conditions: (a) K_2CO_3 , DMF, 80 °C, 8 h; (b) $SnCl_2$, HCl, MeOH, reflux, 8 h; (c) H_2SO_4 , MeOH, reflux, 4 h; EtOAc, K_2CO_3 , 40 °C, overnight; (d) $Pd(PPh_3)_4$, toluene, K_2CO_3 , 4-(methylthio)phenylboronic acid, reflux, 48 h; (e) *m*-CPBA, DCM, 0 °C to room temperature.

3'-(diethylamino)-7'-hydroxyspiro[isobenzofuran-1(3*H*),9'-[9*H*]-xanthen]-3-one through three steps with a moderate yield. The detailed reaction reagents and conditions are depicted in Scheme 2. By using a Suzuki coupling reaction in the presence of 4-methylthiophenylboronic acid, compound **RBS** was yielded as a light blue compound (78%). Followed by the oxidation of the sulfur group in compound **RBS** by using *m*-CPBA as an oxidizing reagent in dry dichloromethane, probe **RBSO** was obtained in 76% yield. The structures of all synthetic compounds were confirmed by HRMS and NMR, and detailed data are presented in the ESI.†

Sensitivity studies

With **RBSO** in hand, we first investigated whether the electron donor DTT could cause interferences in the assay because some molecules with a methyl sulfoxide group can be directly reduced by DTT. Different high concentration DTT (0, 1, 2, 5, 10 mM) and **RBSO** (10 μ M) were interacted at 37 °C (50 mM PBS, pH = 7.4), respectively, and the ratio of the fluorescence intensity (F/F_0) was used to assess the effect of DTT on the probe. As shown in Fig. 1a, there were no interferences in the DTT concentration range of 1–10 mM, indicating that the highly reductive DTT did not respond significantly to the probe and could be used as the electron donor in the next assay. The concentration was fixed at 5 mM in the following assays because DTT could cause negligible fluorescence signal changes at this concentration and was consistent with previous work.¹⁰

In order to test the *in vitro* response of **RBSO** as a potential Msr A sensor, emission spectra were recorded in the presence of various reducing species under the same conditions. As shown in Fig. S16 (ESI†), the absorption maximum of **RBSO** at 596 nm and the fluorescence intensity of **RBSO** at 684 nm decreased remarkably after addition of DTT and Msr A, and furthermore exhibited a large Stokes shift at 88 nm. Meanwhile, the ratio of the fluorescence intensity of the probe at 684 nm ($(F_0 - F)/F_{MsrA}$) was significantly enhanced (Fig. 1b). This spectral phenomenon can be ascribed to the reduction of the methyl sulfoxide to the methyl sulfide group by Msr A, which enabled the transformation of an electron-withdrawing group to an electron-donating group and thus induced the ICT process. In contrast, no significant fluorescence signal change

Fig. 1 (a) **RBSO** (10 μ M) was incubated with DTT (0–10 mM), and the fold of the fluorescence increment (F/F_0) was determined; (b) $(F_0 - F)/F_{MsrA}$ was determined after interaction of different analytes with **RBSO** (10 μ M), including (1) BSA (200 nM), (2) DTT (5 mM), (3) Cys (1 mM), (4) GSH (5 mM), (5) blank, (6) Hcy (1 mM), (7) GR/NADH (200 nM), (8) Vc (5 mM), (9) ethanethiol (5 mM), (10) Trx (200 nM), (11) TCEP (5 mM), (12) DTT + Msr B (5 mM + 3 μ g mL⁻¹), (13) DTT + Msr A (5 mM + 3 μ g mL⁻¹). Conditions: PBS buffer (50 mM, pH 7.4, 37 °C), λ_{ex} = 600 nm, slit = 10/10 nm.

occurred when other thiol substances or reducing substances were added under the same conditions, including bovine serum albumin (BSA), DTT, Cys, GSH, glutathione reductase/NADH (GR/NADH), Hcy, vitamin c (Vc), ethanethiol, Trx, tris(2-carboxyethyl)phosphine (TCEP) and DTT/Msr B. Thus, the above-described results showed that **RBSO** could be specifically reduced by Msr A, resulting in an obvious fluorescence signal change. To verify the response mechanism of **RBSO** towards Msr A, high performance liquid chromatography (HPLC) and high-resolution mass spectra (HRMS) experiments were conducted. As shown in Fig. S17 (ESI[†]), an intense peak at m/z 613.2169 corresponding to **RBS** was distinct, providing reliable evidence for the Msr A-induced reduction. At the same time, this hypothesis was confirmed by HPLC, where a HPLC chromatograph of the pure **RBSO** showed a retention time of 4.07 min, and a new peak of **RBSO** treated with DTT and Msr A appeared clearly at a retention time of 6.21 min (Fig. S18, ESI[†]). The new peak corresponds to the formation of **RBS** because the retention time of the standard sample **RBS** is 6.21 min.

Subsequently, in order to explore whether the probe could be used to monitor Msr A in real-time, time-dependent fluorescent responses of **RBSO** to enzyme were evaluated under physiological environments. After the addition of different concentrations (0 and $3 \mu\text{g mL}^{-1}$) of Msr A under the same conditions, the fluorescence intensity of the probe at 684 nm was recorded and is depicted in Fig. 2a. As shown in Fig. 2a, in the absence of Msr A, the fluorescence intensity of the probe at 684 nm remained substantially constant within 20 minutes, indicating that **RBSO** had high photo-stability. In contrast, upon addition of Msr A ($3 \mu\text{g mL}^{-1}$), the fluorescence intensity of the probe at 684 nm rapidly decreased and reached a plateau within about 8 min, suggesting that **RBSO** could be used as an effective candidate for monitoring Msr A in real-time under physiological environments.

The K_m and K_{cat} values are also key parameters for probes, so we subsequently calculated the K_m and K_{cat} of **RBSO** under

physiological environments. As shown in Fig. 2b, the K_m ($72 \mu\text{M}$) and K_{cat} (6.2 s^{-1}) values of **RBSO** can be calculated by the Michaelis–Menten kinetics. Gratifyingly, compared with the K_m and K_{cat} of other fluorescent probes reported, the properties of **RBSO** have been further improved. As shown in Table S1, the response time of **RBSO** is 8 minutes, while other probes required 30, 60 and 360 minutes, respectively, implying that the response time has been greatly improved. Furthermore, by comparing the reduction rates of different probes by Msr A, it was found that the reduction rate of **RBSO** was almost 10 times that of others reported.¹⁰ The above results demonstrated that **RBSO** can function as a highly selective fluorescent probe for Msr A, and has the potential for monitoring Msr A activity in real-time.

In addition, in order to further confirm that Msr A consumes **RBSO**, different doses of dimethyl sulfoxide (DMSO) and methionine sulfoxide (MetSO) were utilized to inhibit the reduction of **RBSO**. According to the literature,¹⁶ the presence of DMSO and MetSO inhibited the reduction of probes due to the competition between the sulfoxide groups of DMSO and MetSO. The corresponding time-dependent fluorescence responses of **RBSO** to enzymes in the presence of DMSO and MetSO are described in Fig. 2c and d, respectively. Compared to the treatment with pure Msr A, upon the addition of different concentrations of DMSO or MetSO under the same conditions, they had obvious interference with signal response to Msr A, indicating that the presence of DMSO or MetSO affect the consumption of the probe. Furthermore, the effects of pH on the reaction system were investigated (Fig. S19, ESI[†]), which revealed that **RBSO** functioned well under physiological conditions. Collectively, the above-described results suggested that **RBSO** could be used as a practical probe for the specific detection of Msr A in real-time under physiological environments.

Cell imaging

To examine the feasibility of using **RBSO** as an imaging reagent to map the activity of Msr A, cell imaging applications of **RBSO** for monitoring Msr A in living cells were carried out. Prior to cell imaging assays, standard MTT assay was performed to assess the cytotoxicity of **RBSO** in human cervix carcinoma HeLa cells. As shown in Fig. S20 (ESI[†]), HeLa cells treated with various concentrations of **RBSO** (0, 1, 3, 5, 10, and $20 \mu\text{M}$) for 24 h showed high cell viability (no less than 80%), indicating that the probe has fairly low toxicity to living cells, and thus, **RBSO** is suitable as an imaging reagent. Subsequently, imaging experiments of **RBSO** for monitoring Msr A in living cells were conducted. Since the cells contain Msr A, there is no need to add Msr A in cell imaging experiments. HeLa cells were incubated with **RBSO** ($0.1 \mu\text{M}$) for 30 minutes, and then washed three times with PBS to remove excess probes. As shown in Fig. 3a, weak red fluorescence signals were observed in the red channel. In contrast, when the HeLa cells were pretreated with DMSO ($10 \mu\text{L}$), a significant enhancement of the fluorescence signal in the red channel was observed because the reduction of **RBSO** was obviously inhibited (Fig. 3b). Compared with the controlled cells, the relative decrease of fluorescence signals is about 4-fold (Fig. 3c). The results indicated that **RBSO** was

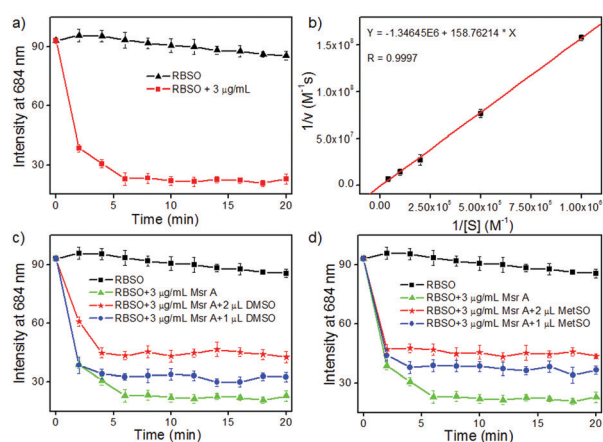

Fig. 2 (a) Time course of **RBSO** ($10 \mu\text{M}$) fluorescence changes in the absence/presence of Msr A ($3 \mu\text{g mL}^{-1}$) and DTT (5 mM); (b) Lineweaver–Burk plot for the enzymatic reduction of **RBSO** catalyzed by Msr A. Inhibition of Msr A-mediated reduction of **RBSO** by DMSO (c) and MetSO (d). **RBSO** ($10 \mu\text{M}$) was incubated with DTT (5 mM) and Msr A ($3 \mu\text{g mL}^{-1}$) with or without DMSO and MetSO. Conditions: PBS buffer (50 mM , $\text{pH } 7.4$, 37°C), $\lambda_{\text{ex}} = 600 \text{ nm}$, slit = $10/10 \text{ nm}$.

Fig. 3 Fluorescence images of HeLa cells stained with **RBSO** (0.1 μ M). (a) Cells were incubated with **RBSO** for 30 min; (b) cells were pretreated with DMSO (10 μ L), and then incubated with **RBSO** for 30 min; and (c) Histogram of fluorescence enhancement. $\lambda_{\text{ex}} = 559$ nm, $\lambda_{\text{em}} = 650$ –750 nm.

membrane permeable and could be used for imaging Msr A in living cells.

By carefully observing the overlay images of the red channel and the bright field, non-uniform intracellular fluorescence signals were noticed, implying that **RBSO** was likely to target organelles. Therefore, in order to verify whether **RBSO** has the desired organelle localization properties, we utilized commercial targeting reagents Lyso-Tracker Green (Lyso), Mito-tracker Green (Mito), and ER-Tracker Green (ER) to explore the organelle-targeting of **RBSO**. Surprisingly, a high Pearson's coefficient (0.93) and overlap coefficient (0.93) were found in the intensity scatter plot of the green channel and red channel, suggesting that **RBSO** distributed mainly in lysosomes. In addition, the intensity scatter plot allowed us to highlight the corresponding yellow pixels on simulated images in accordance with the overlay image (Fig. 4a), and the changes in the intensity profiles in the linear region of interest across the cell were synchronous in the two channels (Fig. S21, ESI[†]). According to that reported previously,¹⁷ moderate alkalinity of the nitrogen atom is critical for its specific localization in acidic lysosomes. Once **RBSO** diffuses into

lysosomes and is protonated, it becomes more hydrophilic and is retained in the lysosomes. In contrast, an obvious difference of the location between the fluorescence from other trackers (Mito and ER) and **RBSO** was observed (Fig. 4b and c). Similarly, low Pearson's coefficients and overlap coefficients were found in the intensity scatter plot, implying that **RBSO** does not accumulate in these organelles. These results suggest that **RBSO** can be used as an efficient organelle-targetable NIR probe for lysosomal Msr A imaging in living cells. Taken together, considering its low cytotoxicity and the excellent performance in cell imaging, the probe may be operated well in monitoring the activity of Msr A in the lysosome of living cells.

Conclusions

In summary, we designed and synthesized a novel lysosome-targeted NIR fluorescent probe **RBSO** for fast detection and imaging Msr A by extending the linear π -conjugated system of the probe *via* the S_NAr^H reaction. As expected, **RBSO** exhibited high selectivity and high sensitivity for the specific detection of Msr A in real-time *via* a specific reduction reaction. Importantly, **RBSO** was cell-membrane permeable and capable of specifically distributing in lysosomes, and thus detects Msr A in real-time there, providing a potential tool for monitoring Msr A activity in lysosomes of living cells.

Experimental

Synthetic procedures

Synthesis of compound 1. 3'-(Diethylamino)-7'-hydroxyspiro-[isobenzofuran-1(3H),9'-(9H)]xanthene-3-one (688.6 mg, 2.2 mmol),¹⁸ anhydrous potassium carbonate (828 mg, 6 mmol) and 4-bromo-1-fluoro-2-nitrobenzene (438 mg, 2 mmol) were added to DMF (10 mL) and stirred under argon at 80 $^{\circ}$ C overnight. After cooling to room temperature, the mixture was extracted with DCM (50 mL \times 3). The collected organic phase was dried over anhydrous sodium sulfate and concentrated to dryness under vacuum. The crude product was isolated and purified by a silica gel column to afford yellow solid intermediate compound **1** (478 mg, 81% yield). ^1H NMR (400 MHz, CDCl_3) δ 8.06–7.98 (m, 2H), 7.73–7.68 (m, 1H), 7.66–7.61 (m, 1H), 7.58–7.52 (m, 1H), 7.36–7.30 (m, 1H), 7.25–7.22 (m, 1H), 7.10–7.06 (m, 1H), 6.81–6.74 (m, 1H), 6.63–6.54 (m, 2H), 6.49 (s, 1H), 6.41 (dd, $J = 6.1, 2.6$ Hz, 1H), 3.39 (dd, $J = 8.7, 3.7$ Hz, 4H), 1.21 (dt, $J = 10.4, 4.3$ Hz, 6H). ^{13}C NMR (100 MHz, CDCl_3) δ 169.32, 152.75, 152.60, 150.45, 149.81, 149.66, 149.23, 140.80, 137.09, 135.15, 129.89, 128.81, 128.43, 126.81, 125.12, 124.01, 122.33, 121.30, 120.36, 119.19, 119.06, 114.51, 108.73, 104.21, 97.54, 83.54, 44.53, 12.52. HRMS $m/z = 589.0903$ calcd. for $\text{C}_{30}\text{H}_{24}\text{N}_2\text{O}_4\text{Br}^+$ [$\text{M}]^+$, found: 589.0815.

Synthesis of compound 2. Concentrated hydrochloric acid (1 mL) was added to a mixed solution of compound **1** (1.12 g, 2 mmol) and stannous chloride (2.25 g, 10 mmol) in methanol (20 mL), and the mixture was heated under reflux for 8 hours with vigorous stirring. After cooling to room temperature, the mixture was extracted with DCM (50 mL \times 3) and the collected

Fig. 4 Fluorescence imaging of the HeLa cells being co-stained with **RBSO** (0.1 μ M) and other organelle-targeting Trackers (200 nM). (a) Co-stained with Lyso-Tracker Green; (b) co-stained with Mito-Tracker Green; and (c) co-stained with ER-Tracker Green. Red channel: $\lambda_{\text{ex}} = 559$ nm, $\lambda_{\text{em}} = 647$ –747 nm. Green channel: $\lambda_{\text{ex}} = 488$ nm, $\lambda_{\text{em}} = 520$ –546 nm.

organic phase was dried over anhydrous sodium sulfate. The dried mixture was concentrated under vacuum, and the crude product was separated and purified by a silica gel column to afford yellow solid intermediate compound **2** (885 mg, 77% yield). ^1H NMR (400 MHz, CDCl_3) δ 8.00 (d, $J = 7.5$ Hz, 1H), 7.67 (t, $J = 7.4$ Hz, 1H), 7.61 (t, $J = 7.3$ Hz, 1H), 7.21 (dd, $J = 8.1, 5.5$ Hz, 2H), 6.91 (dd, $J = 9.0, 2.7$ Hz, 1H), 6.87 (d, $J = 2.0$ Hz, 1H), 6.74–6.67 (m, 1H), 6.58 (d, $J = 8.5$ Hz, 1H), 6.52 (d, $J = 8.5$ Hz, 1H), 6.47 (d, $J = 2.7$ Hz, 2H), 6.39 (s, 1H), 3.82 (s, 2H), 3.36 (dd, $J = 13.7, 6.8$ Hz, 4H), 1.18 (t, $J = 7.0$ Hz, 6H). ^{13}C NMR (100 MHz, CDCl_3) δ 169.42, 152.97, 152.83, 151.77, 149.74, 147.85, 142.81, 139.54, 134.92, 129.71, 128.86, 127.03, 125.06, 123.96, 121.00, 120.76, 119.96, 119.70, 118.64, 118.31, 117.13, 116.83, 108.52, 97.59, 83.92, 60.40, 44.52, 14.22, 12.52. HRMS $m/z = 559.1061$ calcd. for $\text{C}_{30}\text{H}_{26}\text{N}_2\text{O}_4\text{Br}^+ [\text{M}]^+$, found: 559.1064.

Synthesis of compound RB. Concentrated sulfuric acid (1 mL) was added to a mixed solution of the compound **2** (1.13 g, 2 mmol) in methanol (20 mL), and the mixture was heated under reflux for 4 hours under vigorous stirring. After cooling to room temperature, the mixture was extracted with DCM (50 mL \times 3). The collected organic phase was dried over anhydrous sodium sulfate and concentrated to dryness under vacuum. Then, anhydrous potassium carbonate (138 mg, 1 mmol) and ethyl acetate (6 mL) were added and stirred at 40 °C overnight. After cooling to room temperature, the mixture was extracted with ethyl acetate (50 mL \times 3), and the organic phase was collected and dried over anhydrous sodium sulfate. The mixture was concentrated in a rotary evaporator to remove the solvent, and the crude product was purified by a silica gel column to afford blue solid compound **RB** (292 mg, 51% yield). ^1H NMR (400 MHz, CDCl_3) δ 8.30 (d, $J = 7.6$ Hz, 1H), 7.77 (dt, $J = 21.9, 7.3$ Hz, 2H), 7.27 (s, 1H), 7.12 (s, 1H), 7.00 (d, $J = 9.6$ Hz, 2H), 6.85–6.75 (m, 2H), 6.72 (s, 1H), 6.38 (d, $J = 8.5$ Hz, 1H), 6.15 (s, 1H), 3.69 (s, 3H), 3.57 (dd, $J = 14.2, 7.0$ Hz, 4H), 1.31 (t, $J = 7.0$ Hz, 6H). ^{13}C NMR (100 MHz, CDCl_3) δ 165.41, 160.08, 159.69, 157.52, 155.98, 155.10, 142.96, 142.19, 133.63, 133.26, 131.50, 130.50, 129.99, 129.63, 126.92, 118.82, 117.14, 116.89, 116.69, 116.58, 114.96, 114.63, 114.03, 110.10, 99.66, 96.31, 52.67, 46.05, 12.54. HRMS $m/z = 571.1061$ calcd. for $\text{C}_{31}\text{H}_{26}\text{N}_2\text{O}_4\text{Br}^+ [\text{M}]^+$, found: 571.1013.

Synthesis of compound RBS. Compound **RB** (1 mmol, 568 mg), 4-methylthiophenylboronic acid (1.1 mmol, 185 mg), potassium carbonate (3 mmol, 414 mg) and $\text{Pd}(\text{PPh}_3)_4$ (0.03 mmol, 30 mg) were placed in a two-necked round bottom flask and argon gas protection was carried out using a Schlenk line. Then, 15 mL of toluene was added as a solvent using a syringe, and the reaction system was heated to 100 °C for 36 hours. The reaction mixture was cooled to room temperature and poured into 50 mL of water. The mixture was extracted with water and dichloromethane (50 mL \times 3) and the organic phase was dried over anhydrous sodium sulfate. The mixture was concentrated in a rotary evaporator to remove the solvent, and the crude product was purified by a silica gel column to afford blue solid product **RBS** (477 mg, yield 78%). ^1H NMR (400 MHz, CDCl_3) δ 8.19 (d, $J = 7.7$ Hz, 1H), 7.69 (dd, $J = 10.5, 4.2$ Hz, 1H), 7.60 (t, $J = 7.0$ Hz, 1H), 7.46 (d, $J = 8.1$ Hz, 2H), 7.34 (s, 1H), 7.31–7.26 (m, 3H), 7.07–6.97 (m, 1H), 6.67–6.53 (m, 3H), 6.48 (s, 1H), 6.39 (t, $J = 12.1$ Hz, 1H),

5.75 (s, 1H), 3.69 (s, 3H), 3.41 (d, $J = 6.8$ Hz, 4H), 2.50 (s, 3H), 1.21 (t, $J = 6.6$ Hz, 6H). ^{13}C NMR (100 MHz, CDCl_3) δ 166.08, 156.43, 154.72, 150.83, 150.80, 144.47, 144.35, 144.30, 144.17, 144.01, 136.53, 135.46, 132.91, 132.85, 131.10, 130.91, 130.57, 129.08, 127.64, 126.96, 126.92, 123.54, 119.22, 114.75, 112.63, 109.99, 104.48, 102.39, 102.31, 96.94, 52.42, 44.97, 15.96, 12.65. HRMS $m/z = 613.2161$ calcd. for $\text{C}_{38}\text{H}_{33}\text{N}_2\text{O}_4\text{S}^+ [\text{M} + \text{H}]^+$, found: 613.2169.

Synthesis of compound RBSO. Upon addition of *m*-CPBA (0.5 mmol, 86 mg) to compound **RBS** (0.5 mmol, 306 mg) in dry dichloromethane in an ice bath, the temperature naturally increased to room temperature, and the reaction was carried out for 5 hours under vigorous stirring. After removing the solvent under vacuum, the crude product was purified by a silica gel column to afford blue solid product **RBSO** (238 mg, 76% yield). ^1H NMR (400 MHz, CDCl_3) δ 8.24 (d, $J = 7.8$ Hz, 1H), 8.13 (s, 0.5H), 8.02 (d, $J = 5.5$ Hz, 0.5H), 7.75 (t, $J = 7.4$ Hz, 1H), 7.71–7.60 (m, 5H), 7.43 (s, 1H), 7.10 (s, 1H), 7.01 (d, $J = 7.6$ Hz, 1H), 6.79 (d, $J = 9.0$ Hz, 1H), 6.61 (dd, $J = 13.4, 9.2$ Hz, 3H), 5.97 (s, 1H), 3.68 (s, 3H), 3.46 (dd, $J = 13.8, 6.8$ Hz, 4H), 2.73 (s, 3H), 1.24 (t, $J = 6.9$ Hz, 6H). ^{13}C NMR (100 MHz, CDCl_3) δ 165.62, 156.72, 156.00, 152.85, 152.79, 144.14, 143.93, 143.91, 142.71, 135.99, 134.52, 133.55, 132.97, 131.24, 130.43, 129.89, 128.75, 129.05, 129.02, 128.91, 127.94, 127.50, 123.97, 123.44, 118.51, 118.45, 118.41, 118.39, 117.98, 117.95, 115.26, 113.29, 112.35, 112.28, 107.39, 107.36, 107.33, 100.70, 96.58, 52.48, 45.42, 43.96, 12.60. HRMS $m/z = 629.2110$ calcd. for $\text{C}_{38}\text{H}_{33}\text{N}_2\text{O}_5\text{S}^+ [\text{M} + \text{H}]^+$, found: 629.2118.

Cell culture and fluorescence imaging

HeLa cells were cultured in DMEM medium supplemented with 10% (v/v) fetal bovine serum and penicillin/streptomycin (100 $\mu\text{g mL}^{-1}$) in an atmosphere of 5% CO_2 at 37 °C. Then, HeLa cells were seeded in a 24-well plate, cultured in an incubator for 2 hours to adhere to the plate, and then subjected to fluorescence imaging experiments. In the treated group, the cells were incubated with **RBSO** (0.1 μM) for 30 min. In the controlled group, the cells were pre-incubated with DMSO for half an hour. Then, the probe was added and incubated for an additional half an hour. For co-localization experiments, **RBSO** (0.1 μM) was incubated with 200 nM of Mito-Tracker Green (Mito), Lyso-Tracker Green (Lyso), and ER-Tracker Green (ER) for 30 minutes, respectively. Fluorescence imaging experiments were performed on a confocal laser scanning microscope after washing three times with PBS buffer.

Conflicts of interest

There are no conflicts to declare.
