# Enhanced chemical looping CO<sub>2</sub> conversion activity and thermal stability of perovskite LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> by Al substitution†

Yoshihiro Goto, \* Kiyoshi Yamazaki,\* Masashi Kikugawa and Masakazu Aoki

The reverse water–gas shift chemical looping (RWGS-CL) process that utilizes redox reactions of metal oxides is promising for converting CO<sub>2</sub> to CO at low temperatures. Metal oxides with perovskite structures, particularly, perovskite LaCoO<sub>3</sub> are promising frameworks for designing RWGS-CL materials as they can often release oxygen atoms topotactically to form oxygen vacancies. In this study, solid solutions of perovskite LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> (0 ≤ x ≤ 1), which exhibited high CO production capability and thermal stability under the RWGS-CL process, were developed. Al-substituted LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> (x = 0.5) exhibited a 4.1 times higher CO production rate (2.97 × 10<sup>-4</sup> CO mol g<sup>-1</sup> min<sup>-1</sup>) than that of LaCoO<sub>3</sub> (x = 0; 0.73 × 10<sup>-4</sup> CO mol g<sup>-1</sup> min<sup>-1</sup>). Diffuse reflectance infrared Fourier transform spectroscopy studies suggested that an increase in CO<sub>2</sub> adsorption sites produced by the coexistence of Al and Co was responsible for the enhancement of CO production rate. Furthermore, LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> maintained its perovskite structure during the RWGS-CL process at 500 °C without significant decomposition, whereas LaCoO<sub>3</sub> decomposed into La<sub>2</sub>O<sub>3</sub> and Co<sup>0</sup>. In situ X-ray diffraction study revealed that the high thermal stability was attributed to the suppression of phase transition into a brownmillerite structure with ordered oxygen vacancies. These findings provide a critical design approach for the industrial application of perovskite oxides in the RWGS-CL processes.

## Introduction

The development of technologies to convert carbon dioxide (CO<sub>2</sub>) into valuable compounds is essential for mitigating anthropogenic global warming and meeting the growing demand for energy and chemical products. The global CO<sub>2</sub> emissions have increased annually, reaching an all-time high in 2022 (36.8 Gt per year from energy combustion and industrial process).<sup>1</sup> Carbon capture and storage technologies<sup>2–4</sup> are being actively investigated to reduce the CO<sub>2</sub> emissions; however, currently, the annual amount of storage capacity (243.97 Mt in 2022)<sup>5</sup> is only 0.66% of the global CO<sub>2</sub> emissions, resulting in most of the emissions being released into the atmosphere. Capturing this atmospheric CO<sub>2</sub> using direct air capture technologies<sup>6</sup> and utilizing it can indirectly mitigate the global CO<sub>2</sub> emissions.<sup>7</sup>

A possible first step in utilizing captured CO<sub>2</sub> is to convert it into carbon monoxide (CO), which serves as a crucial raw material for synthetic fuels and various chemical products.<sup>8</sup> This conversion is generally carried out by a catalytic reverse water–gas shift reaction (RWGS reaction; CO<sub>2</sub> + H<sub>2</sub> → CO + H<sub>2</sub>O), which requires high temperature due to thermodynamic constraints.<sup>9</sup> For example, temperatures greater than 750 °C are required to achieve a CO<sub>2</sub> conversion of 80%. To decrease this operating temperature, the RWGS chemical looping (RWGS-CL) process using metal oxides has been actively investigated in recent years.<sup>10</sup> The RWGS-CL process consists of sequential reactions of reduction (MO<sub>x</sub> + δH<sub>2</sub> → MO<sub>x-δ</sub> + δH<sub>2</sub>O) and re-oxidation (MO<sub>x-δ</sub> + δCO<sub>2</sub> → MO<sub>x</sub> + δCO) of metal oxides. In contrast to catalytic RWGS reaction, which uses a mixture of H<sub>2</sub> and CO<sub>2</sub> in a certain ratio, the RWGS-CL process is not limited by thermodynamic constraints because the reduction and the oxidation processes are separate, exhibiting the potential for high CO<sub>2</sub> conversion even at low temperatures (<500 °C).<sup>11</sup> Moreover, continuous CO production is achieved by using a fixed bed system in which H<sub>2</sub> and CO<sub>2</sub> are alternately provided to two reactors filled with metal oxides (Fig. 1a) or a circulating fluidized bed system (Fig. 1b) in which the metal oxides are circulated between the oxidation and the reduction reactors.<sup>12</sup>

**Fig. 1** CO production flowchart based on reverse water–gas shift reaction chemical looping (RWGS-CL) process using (a) periodically operated fixed bed system and (b) circulating fluidized bed system.

These systems do not require a water separation process for the produced CO and do not generate methane as a common by-product, resulting in the RWGS-CL process demonstrating higher energy efficiency than the catalytic RWGS reaction.<sup>13</sup>

The performance of the RWGS-CL process is substantially affected by the metal oxides that are responsible for the reduction and re-oxidation reactions. Metal oxides, where some transition metals (*e.g.*, Mn, Fe, Co, and Ni)<sup>14–17</sup> and some triels (In and Ga)<sup>11,18</sup> act as redox species, have been reported as materials for the RWGS-CL process (RWGS-CL materials). To produce CO in the oxidation process with CO<sub>2</sub>, RWGS-CL materials are required to form a large number of oxygen vacancies, which work as active sites for CO<sub>2</sub> conversion, in the reduction process with H<sub>2</sub>.<sup>19</sup> Metal oxides with perovskite structures can often release oxygen atoms topotactically to form oxygen vacancies; hence, they are promising frameworks for designing RWGS-CL materials. In particular, perovskite LaCoO<sub>3</sub>, which demonstrates catalytic RWGS reaction activity,<sup>20</sup> is capable of stabilizing a large number of oxygen vacancies.<sup>21</sup> However, LaCoO<sub>3</sub> is not suitable for the RWGS-CL process because of its poor thermal stability in a reducing atmosphere (decomposition starts at 500 °C).<sup>22</sup> We recently demonstrated that the thermal stability of perovskite LaNiO<sub>3</sub> can be enhanced by Al substitution of a Ni site.<sup>23</sup> In this study, we attempted Al substitution of a Co site in perovskite LaCoO<sub>3</sub> and investigated the effects of Al substitution on thermal stability in a reducing atmosphere and RWGS-CL performance. Al substitution enhanced the thermal stability and prevented phase decomposition at a typical operating temperature of 500 °C during the RWGS-CL process. Notably, although the number of oxygen vacancies formed in LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> decreased with increasing Al substitution, the CO production rate increased. LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> did not exhibit any degradation after 32 cycles of the RWGS-CL stability test, indicating that LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> has potential as a RWGS-CL material.

## Experimental

Polycrystalline LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> ( $x = 0, 0.25, 0.5, 0.75, \text{ and } 1$ ) solid solution samples were prepared using the polymerized

complex method. La(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O (99.9%, FUJIFILM Wako Chemicals), Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O (99.9%, FUJIFILM Wako Chemicals), Al(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O (99.997%, Sigma-Aldrich), citric acid (98%, FUJIFILM Wako Chemicals), and ethylene glycol (99%, FUJIFILM Wako Chemicals) were dissolved in a minimum amount of deionized water in a 1:(1 -  $x$ ): $x$ :6:6 molar ratio. The prepared solutions were stirred on a hotplate at 90 °C for 30 min to promote polymerization and at 150 °C until the brown gels dried. The obtained gels were preheated at 400 °C for 2 h and then calcined twice at 800 °C for 5 h in air. La<sub>0.6</sub>Ca<sub>0.4</sub>Fe<sub>0.4</sub>Mn<sub>0.6</sub>O<sub>3</sub> and Co/In<sub>2</sub>O<sub>3</sub>, as benchmark RWGS-CL materials, were prepared following procedures described in the literature<sup>11,14</sup> (experimental details are provided in the ESI†).

X-ray diffraction (XRD) patterns of the samples were collected using an Ultima IV X-ray diffractometer (Rigaku) with Cu K $\alpha$  radiation ( $\lambda = 1.54056 \text{ \AA}$ ). The XRD patterns were obtained in the range  $2\theta = 20^\circ\text{--}80^\circ$  in steps of  $0.01^\circ$  at room temperature. In situ synchrotron X-ray diffraction (SXRD) patterns of the samples were obtained using a Debye–Scherrer camera with a two-dimensional detector (PILATUS 100 K) installed in the BL5S2 beamline at the Aichi Synchrotron Radiation Center. The quartz glass capillaries (0.3 mm o.d.) filled with the samples were irradiated with X-rays at a wavelength of  $\lambda = 0.689826 \text{ \AA}$ . The atmosphere in the capillaries was either air or 100% H<sub>2</sub>. Both patterns were obtained at either room temperature or 500 °C. The collected XRD and *in situ* SXRD patterns were analyzed using the Le Bail method implemented in JANA2006.<sup>24</sup> Diffuse reflectance infrared Fourier transform (DRIFT) spectra of samples were recorded at 500 °C under a flow of 5% CO<sub>2</sub>/N<sub>2</sub> (200 mL min<sup>-1</sup>) using an iS50 spectrometer (Thermo Fisher). These samples (40 mg) were preheated at 500 °C for 30 min under a flow of 5% H<sub>2</sub>/N<sub>2</sub> (200 mL min<sup>-1</sup>). Thermogravimetric analysis (TGA) was conducted using a thermogravimeter analyzer (TGA-50, Shimadzu) connected to mass flow controllers. The temperature dependence of the TGA curves of the samples (20 mg) was recorded up to 800 °C at a ramp rate of 10 °C min<sup>-1</sup> under a flow of 5% H<sub>2</sub>/N<sub>2</sub> (100 mL min<sup>-1</sup>). The RWGS-CL performance of the samples (20 mg) was evaluated from the isothermal TGA curves recorded upon switching between a flow of 5% H<sub>2</sub>/N<sub>2</sub> (100 mL min<sup>-1</sup>) and 5% CO<sub>2</sub>/N<sub>2</sub> (100 mL min<sup>-1</sup>) every 30 min at 200–500 °C. The CO production rate was estimated from the weight loss during the initial 30 s under 5% H<sub>2</sub>/N<sub>2</sub>. The amount of CO produced was estimated from the total weight loss after 30 min under a 5% H<sub>2</sub>/N<sub>2</sub> flow. CO production was also confirmed by additional experiments using a fixed bed reactor, in which the reaction gas can be analyzed by mass spectrometry (infiTOF, KANOMAX JAPAN) or Fourier-transform infrared (FT-IR) spectroscopy (Bex-100FT, Best-Sokki).

## Results and discussion

All the XRD patterns of the synthesized samples ( $x = 0, 0.25, 0.5, 0.75, \text{ and } 1$ ) are characterized by a rhombohedral perovs-

Fig. 2 (a) X-ray diffraction (XRD) patterns of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $0 \leq x \leq 1$ ). (b) Lattice volumes of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  as a function of Al content ( $x$ ).

kite structure with a space group of  $R\bar{3}c$  (Fig. 2a). No impurities were observed in any sample. The estimated lattice volumes of the end members were  $V = 335.53(1)$  and  $327.06(2) \text{ \AA}^3$  for the  $x = 0$  and 1 samples, respectively. These values agree with those reported for  $\text{LaCoO}_3$  ( $V = 335.6 \text{ \AA}^3$ )<sup>25</sup> and  $\text{LaAlO}_3$  ( $V = 326.9 \text{ \AA}^3$ )<sup>26</sup> respectively. The lattice volumes (Fig. 2b) of the rhombohedral perovskite phases decrease with increasing Al content ( $x$ ), indicating the successful substitution of Al for Co in  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$ . This is attributed to the smaller ionic radius of  $\text{Al}^{3+}$  ( $0.535 \text{ \AA}$ ) compared to that of  $\text{Co}^{3+}$  ( $0.61 \text{ \AA}$ ).<sup>27</sup> The 111 and 104 primary peaks at approximately  $2\theta = 33^\circ$ , as shown in the  $x = 0$  sample ( $\text{LaCoO}_3$ ), overlapped into one peak with an increase in the Al content (Fig. 2a). This overlap is attributed to the reduction of octahedral tilting in the rhombohedral perovskite structure.<sup>28</sup>

The oxygen release behavior of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  is investigated using TGA, recorded upon heating to  $800 \text{ }^\circ\text{C}$  under a flow of 5%  $\text{H}_2/\text{N}_2$  (Fig. 3). The TGA curve of  $\text{LaAlO}_3$  ( $x = 1$ ) did not exhibit any weight loss upon heating to  $800 \text{ }^\circ\text{C}$ , whereas all the

Fig. 3 Thermogravimetric analysis curves of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $0 \leq x \leq 1$ ) during heating in the flow of 5%  $\text{H}_2/\text{N}_2$ . Black arrows indicate the onset temperature of decomposition.

TGA curves of Co-containing  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $x = 0, 0.25, 0.5, 0.75$ ) exhibited weight losses at  $300\text{--}500 \text{ }^\circ\text{C}$ , indicating that these weight losses were attributed to the oxygen release associated with the reduction of  $\text{Co}^{3+}$ . The amount of weight loss up to  $500 \text{ }^\circ\text{C}$  decreased with an increase in the Al content because of the decrease in the Co content. These weight losses correspond to the reduction of  $\text{Co}^{3+}$  to  $\text{Co}^{2.04\text{--}2.11+}$ . All XRD patterns of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  quenched at  $500 \text{ }^\circ\text{C}$  in the TGA measurements are indexed by their original rhombohedral perovskite structure (space group:  $R\bar{3}c$ ) without any separated phase (Fig. S1†). These observations suggest that Co-containing  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $\text{Co}^{3+}$ ) transform into  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_{3-\delta}$  ( $\text{Co}^{2+}$ ;  $\delta = (1-x)/2$ ) following topotactic oxygen release from their crystal lattices.

The TGA curve of  $\text{LaCoO}_3$  ( $x = 0$ ) exhibited further weight loss in the range  $600\text{--}700 \text{ }^\circ\text{C}$ . The weight loss up to  $700 \text{ }^\circ\text{C}$  ( $9.3 \text{ wt}\%$ ) was 3.0 times higher than that observed up to  $500 \text{ }^\circ\text{C}$  ( $3.1 \text{ wt}\%$ ), suggesting the sequential reduction of  $\text{LaCoO}_3$  ( $\text{Co}^{3+}$ ) into  $\text{LaCoO}_{2.5}$  ( $\text{Co}^{2+}$ ), followed by decomposition into Co ( $\text{Co}^0$ ) and  $\text{La}_2\text{O}_3$ . The Co and  $\text{La}_2\text{O}_3$  phases are shown in the XRD pattern of  $\text{LaCoO}_3$  quenched at  $800 \text{ }^\circ\text{C}$  in the TGA measurements (Fig. S2†), attributing the weight loss at  $600\text{--}700 \text{ }^\circ\text{C}$  to phase decomposition. The phase decomposition temperature (black arrows in Fig. 3) increases with increasing Al content:  $600, 660,$  and  $670 \text{ }^\circ\text{C}$  for  $\text{LaCoO}_3$  ( $x = 0$ ),  $\text{LaCo}_{0.75}\text{Al}_{0.25}\text{O}_3$  ( $x = 0.25$ ), and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  ( $x = 0.5$ ), respectively.  $\text{LaCo}_{0.25}\text{Al}_{0.75}\text{O}_3$  ( $x = 0.75$ ) and  $\text{LaAlO}_3$  ( $x = 1$ ) did not exhibit any significant weight loss in the range  $500\text{--}800 \text{ }^\circ\text{C}$ . The XRD patterns of the samples quenched at  $800 \text{ }^\circ\text{C}$  reveal that undergoes  $\text{LaCo}_{0.75}\text{Al}_{0.25}\text{O}_3$  ( $x = 0.25$ ) partial decomposition, while still maintaining the perovskite phase.  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  ( $x = 0.5$ ),  $\text{LaCo}_{0.25}\text{Al}_{0.75}\text{O}_3$  ( $x = 0.75$ ), and  $\text{LaAlO}_3$  ( $x = 1$ ) does not show any phase decomposition (Fig. S2†). These results show that Al substitution enhances the structural stability of perovskite  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  in a reducing atmosphere.

In situ SXRD measurements were conducted to investigate the reasons for the enhanced structural stability. The SXRD patterns of  $\text{LaCoO}_3$  ( $x = 0$ ) and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  ( $x = 0.5$ ) are

indexed to a rhombohedral perovskite structure (space group:  $R\bar{3}c$ ) without any impurity phases at room temperature in air (Fig. 4). The estimated lattice volumes of  $\text{LaCoO}_3$  and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  ( $V = 335.80(3)$  and  $329.25(4) \text{ \AA}^3$ , respectively, Fig. S3†) agreed with those estimated from the XRD patterns (Fig. 2). Heating these samples to  $500 \text{ }^\circ\text{C}$  in air did not change their crystal structures. Peak shifts toward lower angles were observed for both samples, indicating an increase in the lattice volumes owing to thermal expansions.<sup>29</sup> The lattice volumes of  $\text{LaCoO}_3$  and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  at  $500 \text{ }^\circ\text{C}$  were  $V = 347.80(6)$  and  $336.62(5) \text{ \AA}^3$ , respectively (Fig. S3†), corresponding to thermal expansions of 3.6% and 2.2%, respectively, relative to those at room temperature. The SXRD pattern of  $\text{LaCoO}_3$  obtained 5 min after switching the atmosphere from air to  $\text{H}_2$  at  $500 \text{ }^\circ\text{C}$  is characterized by an orthorhombic brownmillerite structure with a space group of  $Pnma$  and a small amount of  $\text{La}_2\text{O}_3$  (Fig. 4a). The brownmillerite structure was identical to the reported structure of  $\text{LaCoO}_{2.5}$  ( $\text{La}_2\text{Co}_2\text{O}_5$ ), which was produced by the reduction of  $\text{LaCoO}_3$ .<sup>30</sup> The brownmillerite phase observed in the SXRD pattern was identified as  $\text{LaCoO}_{2.5}$ . This determination was based on the estimated composition of  $\text{LaCoO}_3$ , which was found to be reduced at  $500 \text{ }^\circ\text{C}$  in the TGA analysis ( $\text{LaCoO}_{2.52}$ ), resulting in a composition similar to that of  $\text{LaCoO}_{2.5}$ . The peak intensities of the brownmillerite phase decreased 30 min after atmospheric switching, whereas those of  $\text{La}_2\text{O}_3$  increased simultaneously.

**Fig. 4** In situ synchrotron XRD patterns of (a)  $\text{LaCoO}_3$  and (b)  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  collected at room temperature in air,  $500 \text{ }^\circ\text{C}$  in air, and  $500 \text{ }^\circ\text{C}$  in 100%  $\text{H}_2$  (5 and 30 min).

An additional Co metal phase was observed. These observations show that brownmillerite  $\text{LaCoO}_{2.5}$ , which is formed by the reduction of perovskite  $\text{LaCoO}_3$ , gradually decomposes into Co and  $\text{La}_2\text{O}_3$  under a reducing atmosphere at  $500 \text{ }^\circ\text{C}$  (Fig. 5). In contrast, the SXRD pattern of  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  shows that the perovskite phase maintained its original rhombohedral perovskite structure 30 min after switching the atmosphere from air to  $\text{H}_2$  at  $500 \text{ }^\circ\text{C}$  (Fig. 4b). No phase decomposition was observed. Moreover,  $\text{LaCoO}_3$  and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  exhibited an increase in the lattice volumes after switching the atmosphere from air to  $\text{H}_2$  at  $500 \text{ }^\circ\text{C}$  (Fig. S3†). This finding could be attributed to an increase in the ionic radius of Co from  $0.61 \text{ \AA}$  ( $\text{Co}^{3+}$ ) to  $0.745 \text{ \AA}$  ( $\text{Co}^{2+}$ ) owing to the reduction of  $\text{LaCoO}_3$  and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$ . Therefore, *in situ* SXRD measurements suggest that the suppression of phase transition from the perovskite to the brownmillerite structure in a reducing atmosphere is responsible for the enhancement of the structural stability.

The effect of crystallographic differences on structural stability is often explained by the coordination number (CN) of redox species.<sup>23,32</sup> In perovskite  $\text{LaNi}_{1-x}\text{Al}_x\text{O}_3$ , suppression of the formation of  $\text{Ni}^{2+}$  with small CN (four-coordinated  $\text{NiO}_4$ ) in a reducing atmosphere prevents further reduction to  $\text{Ni}^{1+}$ , leading to phase decomposition.<sup>23</sup> All Co atoms in the crystal lattice of  $\text{LaCoO}_3$  and  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  form  $\text{CoO}_6$  octahedra (CN = 6) in an oxidizing atmosphere (Fig. 5). The brownmillerite  $\text{LaCoO}_{2.5}$ , observed for  $\text{LaCoO}_3$  in a reducing atmosphere, has a vacancy-ordered structure comprising original  $\text{CoO}_6$  octahedra and  $\text{CoO}_4$  tetrahedra (CN = 4), where two O atoms were removed from two neighboring octahedra in the perovskite structure; the formation of one tetrahedron that can form a vacancy-ordered structure is energetically more stable than the formation of two pentahedral (CN = 5).<sup>33</sup> In contrast,  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  maintained its original rhombohedral perovskite structure in a reducing atmosphere, indicating that  $\text{CoO}_5$

**Fig. 5** Schematic of the structural changes in (a)  $\text{LaCoO}_3$  and (b)  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  at  $500 \text{ }^\circ\text{C}$ . White, blue, green, and red spheres represent La, Co, Al, and O, respectively. The crystal structures were depicted by VESTA program.<sup>31</sup>

pentahedra rather than  $\text{CoO}_4$  tetrahedra were predominantly formed by the reduction of  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$ . This finding could be attributed to the random substitution of irreducible Al in  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$ , which reduces the number of neighboring  $\text{CoO}_6$  octahedra, preventing oxygen vacancy ordering resulting in the formation of  $\text{CoO}_4$  tetrahedra. Suppression of the formation of  $\text{CoO}_4$  tetrahedra with less CN enhanced the structural stability of  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  in a reducing atmosphere.

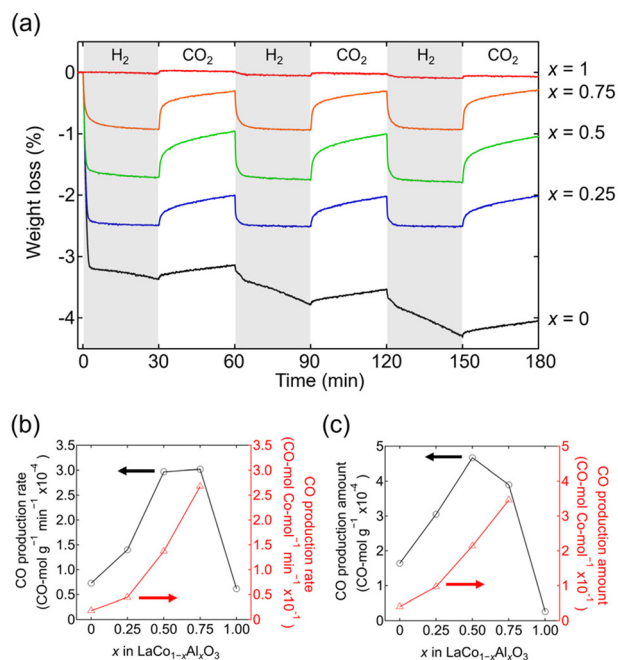

The RWGS-CL performance of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  is evaluated from the weight change upon alternately switching the atmosphere between 5%  $\text{H}_2/\text{N}_2$  and  $\text{CO}_2/\text{N}_2$  every 30 min at an isothermal temperature of 500 °C (Fig. 6a). Co-containing  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $x = 0, 0.25, 0.5$ , and  $0.75$ ) exhibited weight losses in the initial 5%  $\text{H}_2/\text{N}_2$  atmosphere (0–30 min) attributed to the oxygen release associated with  $\text{Co}^{3+}$  reduction. The amount of weight loss decreased with increasing Al content, indicating a decrease in the number of oxygen vacancies formed. The weights of the samples increased again when the atmosphere was switched to 5%  $\text{CO}_2/\text{N}_2$  (30–60 min). The increase in weight was derived from oxygen intake associated with the oxidation of  $\text{Co}^{2+}$ , which resulted in the formation of CO through the reduction of  $\text{CO}_2$ . CO production was also confirmed by mass spectrometry (Fig. S4†) and FT-IR spectroscopy (Fig. S5†). Although these methods can quantify the CO production amount, they are not suitable for quantifying the CO production rate because of the effect of gas diffusion. Thus, CO production is often estimated from weight changes.<sup>11,18</sup> When the atmosphere was subsequently switched again to 5%

$\text{H}_2/\text{N}_2$  (60–90 min), the weight of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $x = 0.25, 0.5$ , and  $0.75$ ) decreased to the same weight as that in the initial 5%  $\text{H}_2/\text{N}_2$  atmosphere (0–30 min), whereas the weight of  $\text{LaCoO}_3$  ( $x = 0$ ) decreased more than that in the initial 5%  $\text{H}_2/\text{N}_2$  atmosphere (0–30 min). The RWGS-CL profiles normalized by the fraction of reduced  $\text{Co}^{3+}$  ( $[\text{Co}^{2+}]/([\text{Co}^{2+}] + [\text{Co}^{3+}])$ ) show that the fraction of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $x = 0.25, 0.5$ , and  $0.75$ ) becomes constant at approximately 100% in 5%  $\text{H}_2/\text{N}_2$ , whereas that of  $\text{LaCoO}_3$  exceeds 100% (Fig. S6†). This finding suggests that  $\text{Co}^{3+}$  in  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $x = 0.25, 0.5$ , and  $0.75$ ) is stabilized by  $\text{Co}^{2+}$  in a reducing atmosphere, whereas  $\text{Co}^{3+}$  in  $\text{LaCoO}_3$  is not stabilized by  $\text{Co}^{2+}$  and is further reduced. The XRD patterns of samples after the RWGS-CL reaction (Fig. S7†) reveal that only  $\text{LaCoO}_3$  contained  $\text{La}_2\text{O}_3$  in addition to its original perovskite phase, indicating that the reduction of  $\text{Co}^{2+}$  is accompanied by a phase separation, which is consistent with the fact that  $\text{LaCoO}_3$  gradually decomposes into Co and  $\text{La}_2\text{O}_3$  in a reducing atmosphere, as revealed by the *in situ* SXRD experiment (Fig. 5). Therefore, the RWGS-CL reaction of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $x = 0.25, 0.5$ , and  $0.75$ ) containing Co and Al corresponds to the following topotactic redox reactions:

The CO production rate per unit mass ( $\text{CO mol g}^{-1} \text{min}^{-1}$ ), which is estimated from the weight change rate in 5%  $\text{CO}_2/\text{N}_2$  at 500 °C, is maximum at  $x = 0.5$ – $0.75$  for  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  (Fig. 6b). For example, the CO production rate of  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  ( $x = 0.5$ ;  $2.97 \times 10^{-4} \text{ CO mol g}^{-1} \text{min}^{-1}$ ) was 4.1 times higher than that of  $\text{LaCoO}_3$  ( $x = 0$ ;  $0.73 \times 10^{-4} \text{ CO mol g}^{-1} \text{min}^{-1}$ ). The higher CO production rate per unit mass despite the lower Co content is derived from the fact that the CO production rate per Co atom ( $\text{CO mol}^{-1} \text{min}^{-1}$ ) increased with increasing Al content (Fig. 6b:  $0 \leq x \leq 0.75$ ). The DRIFT spectra of  $\text{LaCoO}_3$  ( $x = 0$ ) and  $\text{LaCo}_{0.75}\text{Al}_{0.25}\text{O}_3$  ( $x = 0.25$ ) in 5%  $\text{CO}_2/\text{N}_2$  at 500 °C (Fig. S8†) exhibited only one absorption peak at approximately  $2350 \text{ cm}^{-1}$ , corresponding to the  $\text{CO}_2$  gas phase,<sup>34</sup> whereas that of  $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$  ( $x = 0.5$ ) exhibited additional broad peaks at  $1252$  and  $1529 \text{ cm}^{-1}$  derived from carbonate ( $\text{CO}_3^{2-}$ ).<sup>35</sup> However, the adsorption modes of carbonate could not be identified because of the broadness of the peaks. The oxygen atoms required for carbonate formation can come from  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_{3-\delta}$  itself or supplied to  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_{3-\delta}$  during the RWGS-CL reaction in eqn (2).  $\text{LaCo}_{0.25}\text{Al}_{0.75}\text{O}_3$  ( $x = 0.75$ ) had larger peaks at  $1186$  and  $1685 \text{ cm}^{-1}$ , originating from carbonates; however,  $\text{LaAlO}_3$  ( $x = 1$ ) did not exhibit any peaks associated with carbonates. The results of the DRIFT experiments suggest that the coexistence of a suitable amount of Al and Co ( $0.5 \leq x \leq 0.75$ ) in  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  increases the  $\text{CO}_2$  adsorption sites. The increased number of  $\text{CO}_2$  adsorption sites promotes  $\text{CO}_2$  dissociation at an oxygen vacancy as an active site, which in turn enhances the CO production rate.

The CO production amount per unit mass ( $\text{CO mol g}^{-1}$ ) at 500 °C is maximum at  $x = 0.5$  ( $\text{LaCo}_{0.5}\text{Al}_{0.5}\text{O}_3$ ;  $4.67 \times 10^{-4} \text{ CO}$

**Fig. 6** (a) Isothermal RWGS-CL curves of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  ( $0 \leq x \leq 1$ ) under flow of 5%  $\text{H}_2/\text{N}_2$  and  $\text{CO}_2/\text{N}_2$  at 500 °C. (b) CO production rate and (c) CO production amount of  $\text{LaCo}_{1-x}\text{Al}_x\text{O}_3$  estimated from weight gains in 5%  $\text{CO}_2/\text{N}_2$  at 500 °C.

mol g<sup>-1</sup>) for LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> (Fig. 6c). The amount of CO produced per Co atom (CO mol<sup>-1</sup>) increased with an increase in the Al content (0 ≤ x ≤ 0.75) owing to the increase in the CO production rate. A trade-off between the increase in the CO production amount per Co atom and decrease in Co content would result in the maximum CO production amount per unit mass at x = 0.5. Additionally, the temperature dependence of the CO production amount per unit mass in the RWGS-CL reaction was investigated (Fig. S10†). LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> (x = 0, 0.25, 0.5, 0.75, and 1) showed almost no CO production at 200 °C, whereas Co-containing LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> (x = 0, 0.25, 0.5, and 0.75) produced CO at ≥300 °C. Interestingly, Al-substituted LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> (x = 0.25, 0.5, and 0.75) produced more CO than LaCoO<sub>3</sub> (x = 0) at ≥400 °C, indicating the effect of the coexistence of Al and Co. Moreover, the amount of CO producing LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> exhibits no degradation over 32 cycles of the RWGS-CL stability test at 500 °C (Fig. S9†), demonstrating that LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> is usable as a practical RWGS-CL material.

The RWGS-CL performance of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> was then compared with those of perovskite La<sub>0.6</sub>Ca<sub>0.4</sub>Fe<sub>0.4</sub>Mn<sub>0.6</sub>O<sub>3</sub> (LCFMO)<sup>14</sup> and Co/In<sub>2</sub>O<sub>3</sub>,<sup>11</sup> which have been reported to exhibit high CO<sub>2</sub> conversion activity and stability. The order of the CO production rate at 500 °C is LCFMO > LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> > Co/In<sub>2</sub>O<sub>3</sub>, which possibly reflects the order of the number of CO<sub>2</sub> adsorption sites or the activity of oxygen vacancies (Fig. S11a†). The CO production amount of Co/In<sub>2</sub>O<sub>3</sub> (1.90 × 10<sup>-3</sup> CO mol g<sup>-1</sup>) is 4.0 and 3.3 times higher than that of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> (0.47 × 10<sup>-3</sup> CO mol g<sup>-1</sup>) and LCFMO (0.58 × 10<sup>-3</sup> CO mol g<sup>-1</sup>), respectively (Fig. S11b†). This finding is attributed to the fact that the theoretical maximum CO production amount estimated from the content of redox species in Co/In<sub>2</sub>O<sub>3</sub> (In<sup>3+</sup> ↔ In<sup>0</sup>: 17.8 mmol g<sup>-1</sup>) was 8.2 and 3.6 times higher than that of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> (Co<sup>3+</sup> ↔ Co<sup>2+</sup>: 2.18 mmol g<sup>-1</sup>) and LCFMO (Fe<sup>3+</sup> ↔ Fe<sup>2+</sup> and Fe<sup>4+</sup> ↔ Fe<sup>3+</sup>: 4.93 mmol g<sup>-1</sup>), respectively. Notably, the oxygen release rate, an indicator of regeneration rate of samples in H<sub>2</sub> atmosphere, of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> (6.02 × 10<sup>-4</sup> O mol g<sup>-1</sup> min<sup>-1</sup>) is 6.4 and 4.7 times higher than that of LCFMO (0.94 × 10<sup>-4</sup> O mol g<sup>-1</sup> min<sup>-1</sup>) and Co/In<sub>2</sub>O<sub>3</sub> (1.27 × 10<sup>-4</sup> O mol g<sup>-1</sup> min<sup>-1</sup>), respectively (Fig. S11c†). The oxygen release reaction in Co/In<sub>2</sub>O<sub>3</sub> is associated with the formation of Co–In alloys from Co and In<sub>2</sub>O<sub>3</sub>,<sup>11</sup> whereas that in LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> is accompanied by a topotactic reaction (eqn (1): from LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> to LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>2.75</sub>), which does not change the basic crystal structure. The relatively low energy required for oxygen release by the topotactic reaction may explain the higher oxygen release rate of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> than that of Co/In<sub>2</sub>O<sub>3</sub>. Moreover, the higher oxygen release rate of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> over that of LCFMO could be attributed to the fact that Co<sup>3+</sup> is more readily reduced than Fe<sup>3+</sup> and Mn<sup>4+</sup>.<sup>36</sup> The RWGS-CL reaction system is expected to conduct reduction and oxidation reactions in parallel (Fig. 1); hence, RWGS-CL materials are required to exhibit high oxygen release and CO production rates. Therefore, LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub>, with a high oxygen release rate in addition to a high CO production rate, is a suitable material for the RWGS-CL process.

## Conclusions

Solid solutions of LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> (0 ≤ x ≤ 1) with rhombohedral perovskites structure were synthesized using the polymerized complex method. The effect of Al substitution on their thermal stability in a reducing atmosphere and RWGS-CL performance was investigated. Al substitution suppressed the phase transition into a brownmillerite structure with ordered oxygen vacancies and enhanced the thermal stability in a reducing atmosphere. Hence, LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> (x = 0.5) maintained the perovskite structure throughout a 32-cycle RWGS-CL stability test. Moreover, the CO production rate increased with Al substitution. The CO production rate of LaCo<sub>0.5</sub>Al<sub>0.5</sub>O<sub>3</sub> (2.97 × 10<sup>-4</sup> CO mol g<sup>-1</sup> min<sup>-1</sup>) was 4.1 times higher than that of LaCoO<sub>3</sub> (0.73 × 10<sup>-4</sup> CO mol g<sup>-1</sup> min<sup>-1</sup>). This activity enhancement may be derived from the CO<sub>2</sub> adsorption sites generated by the coexistence of Al and Co atoms. This study demonstrated that the substitution of Al, which was not involved in the redox reaction of RWGS-CL, exhibited the ability to enhance thermal stability in a reducing atmosphere and RWGS-CL performance. We believe that further compositional optimization of LaCo<sub>1-x</sub>Al<sub>x</sub>O<sub>3</sub> can lead to its practical application in the RWGS-CL process, thereby facilitating the utilization of CO<sub>2</sub>.
