DOI: 10.1039/d2fd00165a

Transition metal catalysis benefitting from supramolecular interactions in the secondary coordination sphere in order to pre-organize substrates around the active site and reach a specific selectivity typically occurs under long reaction times and mild reaction temperatures with the aim to maximize such subtle effects. Herein, we demonstrate that the kinetically labile Zn···N interaction between a pyridine substrate and a zinc–porphyrin site serving for substrate binding is a unique type of weak interaction that enables identification of supramolecular effects in transition metal catalysis after one hour at a high reaction temperature of 130 °C. Under carefully selected reaction conditions, supramolecularly-regulated palladium-catalyzed Mizoroki–Heck reactions between 3-bromopyridine and terminal olefins (acrylates or styrenes) proceeded in a more efficient manner compared to the non-supramolecular version. The supramolecular catalysis developed here also displayed interesting substrate-selectivity patterns.

## Introduction

The last decades have witnessed how merging transition metal catalysis with supramolecular chemistry has led to a remarkable number of supramolecular catalysts displaying unique reactivities.<sup>1</sup> In fact, supramolecular catalysts aim at controlling catalyst activity and selectivity with tools that are beyond the traditional catalyst modification at the first coordination sphere (*i.e.* steric and electronic parameters of the ligands attached to the metal centre).<sup>2</sup> Such approach resembles to some extent the action mode found in Nature's catalysts, enzymes, in which dynamic binding and kinetically labile, weak interactions are at play to pre-organize substrates around an active site as well as to stabilize or destabilize the desired reaction intermediates.<sup>3</sup> From the many weak interactions that have

† Electronic supplementary information (ESI) available. See DOI: <https://doi.org/10.1039/d2fd00165a>

been employed in metal catalysts featuring substrate pre-organization, hydrogen bonding and ion-pairing have been largely explored.<sup>4</sup> Their binding towards complementary substrates is highly predictable in view to place a specific reactive site of the substrate in close proximity to the catalytically active metal site.<sup>5</sup> This is highly beneficial to tackle selectivity issues associated with challenging chemical reactions.<sup>6</sup>

Alternatively, since many substrates are not prone to undergo hydrogen bonding or ion-pairing, it is appealing to disclose new types of weak interactions that can be explored for supramolecular substrate recognition in the context of transition metal catalysis.<sup>7</sup> In our laboratory, we have been interested in the development of supramolecular metal catalysts comprising a zinc-porphyrin site for molecular recognition with pyridine derivatives *via* kinetically labile, weak Zn $\cdots$ N interactions.<sup>8</sup> In this way, selective iridium-catalyzed C–H borylation at the *meta* position has been disclosed thanks to the ideal pre-organization between the active site and the substrate binding site.<sup>9</sup> We also designed in the past a supramolecular ligand built up around a zinc-porphyrin scaffold that contains a nitrile group in the *ortho* position of each *meso*-substituted phenyl group (L, Fig. 1).<sup>10</sup> In the presence of a palladium precursor such ligand featured interesting substrate-selectivity patterns when applied in Suzuki–Miyaura reactions between bromopyridines and phenylboronic acid at 80 °C. In this case, only the bromopyridine substrate and the ligand are soluble in toluene, an apolar and non-coordinating solvent that maximizes the binding of bromopyridine derivatives to the zinc-porphyrin molecular recognition site whereas the palladium active sites are bound to the nitrile groups in the ligand. In the present study, we decided to evaluate the compatibility of the weak Zn $\cdots$ N interactions at higher reaction temperatures and also in the presence of coupling partners that are soluble in the reaction media and can eventually compete with the bromopyridine substrates for binding the molecular recognition site. As such, we turned our attention to palladium-catalyzed Mizoroki–Heck cross-coupling reactions that typically require a significant higher reaction temperature than the Suzuki–Miyaura ones and,<sup>11</sup> in addition, the acrylate coupling partners are usually soluble in apolar non-coordinating solvents while presenting a carbonyl ester group that is known to bind to zinc-porphyrins, at least in the solid state (Fig. 1).<sup>12</sup> We found out that such catalytic reactions are fast (one hour time) and that acrylates did not perturb the weak Zn $\cdots$ N interaction between the substrate and the molecular recognition site even at higher reaction temperatures of 130 °C.

Pd-catalyzed Suzuki–Miyaura reaction (previous work):

Pd-catalyzed Mizoroki–Heck reaction (*this work*):

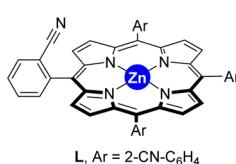

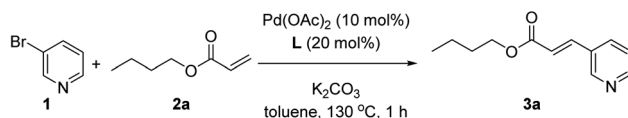

Fig. 1 Previously developed supramolecular ligand L applied in palladium-catalyzed Suzuki–Miyaura reactions and its current application in palladium-catalyzed Mizoroki–Heck cross-coupling reactions.

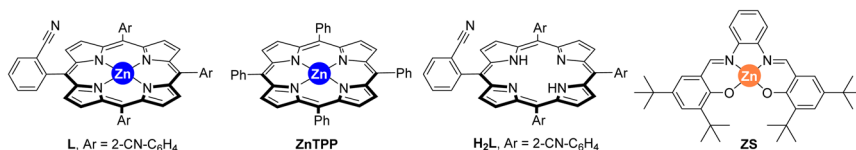

## Results and discussion

As a model reaction we studied the reaction between 3-bromopyridine (**1**) with butyl acrylate (**2a**) in the presence of the supramolecular ligand **L** and catalytic amounts of Pd(OAc)<sub>2</sub> precursor under basic conditions (Table 1). After screening some reaction conditions with different bases and catalyst loadings at different reaction temperatures (Table S1 in the ESI<sup>†</sup>), we noted that at 130 °C the expected product **3a** formed in 78% yield in the presence of 10 mol% pre-catalyst precursor, 20 mol% of ligand **L** and 3 equivalents of both potassium carbonate and coupling partner **2a** (Table 1, entry 1). In toluene solvent, the reaction was finished in one hour since longer reaction times influenced little the conversion of **1** and the formation of **3a**, as was shown in a preliminary kinetic study (Fig. S12 and S13 in the ESI<sup>†</sup>). As it is well-known for Mizoroki–Heck reactions, the temperature had a dramatic effect on the activity since decreasing the temperature led to poor yields of **3a** (Table S1 in the ESI<sup>†</sup>). Under identical reaction conditions, we performed a number of control experiments to assess the action mode of the supramolecular ligand **L**. The influence of covalently linking the nitrile groups to the zinc–porphyrin scaffold was studied by performing a catalytic reaction in the presence of unfunctionalized zinc–tetraphenylporphyrin (**ZnTPP**) at 20 mol% loading and benzonitrile at 80 mol% loading to provide a fair comparison with the use of 20 mol% of **L** in Table 1, entry 1. In this case, the product **3a** formed in 28% yield (Table 1, entry 2). A similar poor reactivity was found by using only **ZnTPP** in the absence of benzonitrile (Table 1, entry 3) or by evaluating the zinc-

<sup>a</sup> Reaction conditions: **1** (7.9 mg, 4.8 μL, 0.05 mmol), **2a** (19.2 mg, 21.6 μL, 0.15 mmol), K<sub>2</sub>CO<sub>3</sub> (20.7 mg, 0.15 mmol), **L** (7.8 mg, 0.01 mol), Pd(OAc)<sub>2</sub> (1.12 mg, 0.005 mmol), toluene (1 mL), 130 °C, 1 h, argon. <sup>b</sup> Yields determined by GC–MS analysis.

free version of **L**, namely **H<sub>2</sub>L** (Table 1, entry 4). Analogously, the reaction performed in the absence of any ligand led to a poor yield of 23% under these reaction conditions (Table 1, entry 5). To further validate that the catalysis occurred with the pyridine derivative bound to the zinc-porphyrin molecular recognition site of **L**, we performed the standard reaction in the presence of 20 mol% of zinc-salphen (**ZS**), which is expected to behave as an inhibitor by coordinating with **1** since the association constant of pyridines with zinc-salphen derivatives is typically two orders of magnitude higher than with zinc-porphyrins (Table 1, entry 6).<sup>8e,13</sup> As anticipated, the reactivity drastically dropped to 5% formation of product **3a** in line with the fact that **1** is trapped by the zinc-salphen building block and cannot approach to the supramolecular palladium catalyst. Alternatively, a similar behaviour was encountered by introducing into the catalysis media a strongly coordinating 4-dimethylaminopyridine (DMAP) compound that is expected to compete with the bromopyridine **1** for binding the molecular recognition site of the supramolecular palladium catalyst (Table 1, entry 7).<sup>14a</sup> Indeed, in the presence of DMAP, the yield of product **3a** also dropped to 42% confirming the inhibitory role of DMAP as well as indirectly suggesting that the catalysis likely occurs with the 3-bromopyridine **1** bound to the molecular recognition site. On the other hand, no reactivity was observed for the reaction between 3-chloropyridine and butyl acrylate (**2a**), whereas the 3-iodopyridine substrate behaved similarly to the 3-bromopyridine affording 60% yield of **3a** using the supramolecular ligand **L**.

To gain insights into the binding ability of the supramolecular ligand **L** under conditions similar to those used in the catalysis presented above, we performed NMR experiments combining equimolar amounts of **L** and the starting material 3-bromopyridine (**1**) in the presence of excess butyl acrylate (**2a**) (Scheme 1). The <sup>1</sup>H NMR spectrum of the resulting mixture showed negligible shifts in the proton signals belonging to **L** and the acrylate **2a** (Fig. S1–S3, S6, S9, S11 in the ESI†). However, the proton signals belonging to the pyridine derivative **1** underwent an important upfield shift, which is in agreement with an interaction between **1** and **L** via Zn···N interaction.<sup>14</sup> This was further evaluated by performing NMR studies at higher temperatures up to 120 °C (Fig. 2). In addition, DOSY experiments show that 3-bromopyridine (**1**) diffuses together with the supramolecular ligand **L** in the presence of acrylate **2a**, which displays a different diffusion coefficient (Fig. S4–S5, S7–S8, S10 in the ESI†).<sup>15</sup> Remarkably, the self-assembly ligand-to-substrate [**L** ⊂ **1**] appears to be rather stable at high temperatures even in the presence of competing ester groups from **2a**. It is clear that, in the present case,

**Scheme 1** Equilibria involving the supramolecular ligand **L** in the presence of bromopyridine **1** and acrylate **2a**.

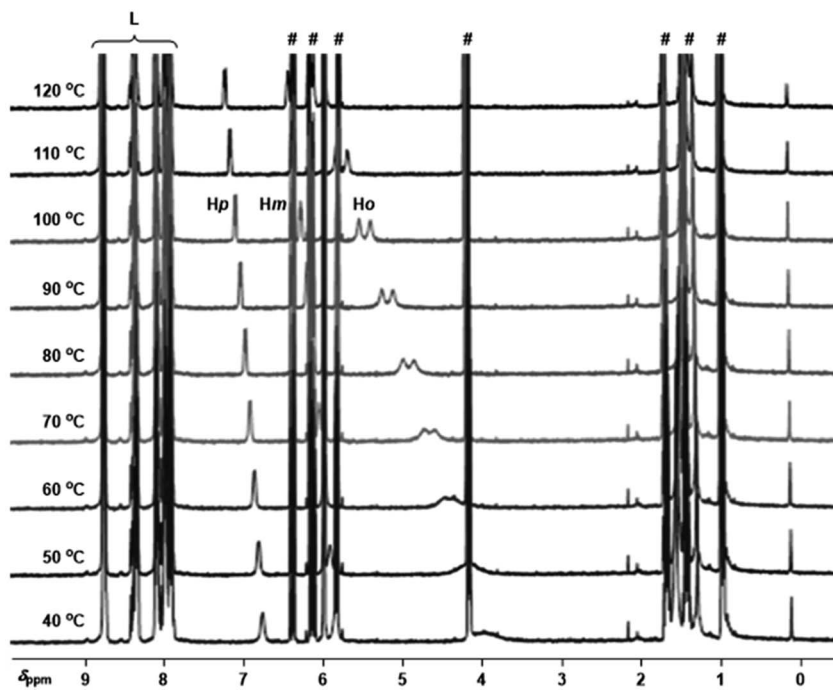

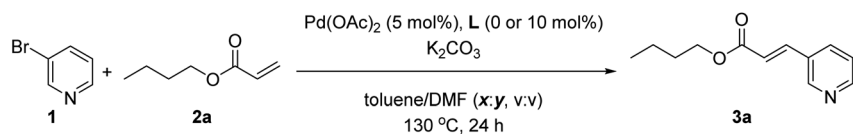

Fig. 2 Variable temperature  $^1\text{H}$  NMR (1,1,2,2-tetrachloroethane- $d_2$ , 400 MHz) spectra for the combination of **L** with **1** in the presence of excess **2a** (for proton numbering see Scheme 1, # marks denote the proton signals belonging to the acrylate derivative **2a** and **L** are the proton signals belonging to the supramolecular ligand **L**, and for concentration details see the ESI†).

the ester groups are not sufficiently coordinating towards zinc to enable the displacement of the pyridine derivative **1** from the molecular recognition site of **L** even at high temperatures.

In order to study the eventual possibility to cleave the  $\text{Zn}\cdots\text{N}$  interaction between the pyridine substrate **1** and the supramolecular ligand **L**, we decided to introduce a stronger coordinating species than acrylates in the reaction medium during the palladium-catalyzed Mizoroki–Heck reaction. For that, we used *N,N*-dimethylformamide (DMF) as a co-solvent together with toluene with a half catalyst loading compared to that used in Table 1. As shown in Table 2, the supramolecular effect of **L** decreased with increasing quantities of DMF co-solvent reaching a negligible supramolecular effect when the amount of DMF was 50% in volume and beyond (Table 2, entries 4–6). With this large excess of DMF, the well-known palladium nanoparticles regime is likely operating.<sup>16</sup> Interestingly, it is relevant to note that the supramolecular effect of **L** was evidenced when the amount of DMF was lower than 50% in volume (Table 2, entries 1–3). For instance, performing the catalysis with DMF at 20% volume ratio led to an almost six-fold increase in the reactivity when compared to the non-supramolecular version (Table 2, entry 1). This finding is particularly relevant since it demonstrates that it is possible to benefit from remote  $\text{Zn}\cdots\text{N}$  weak interactions in metal catalysis even under such unfavourable reaction conditions regarding the nature

**Table 2** Influence of the polar and highly coordinating solvent DMF in the palladium-catalyzed Mizoroki–Heck cross-coupling of 3-bromopyridine (**1**) with butyl acrylate (**2a**) in the presence or absence of the supramolecular ligand **L**<sup>a</sup>

of the solvent and the high reaction temperature, thereby enabling enlargement of the polarity window of solvents that can be used in supramolecular catalysis.

Next, the influence of the nature of the olefin derivative was studied by using different types of acrylate derivatives as well as styrene derivatives for the reaction with the 3-bromopyridine (**1**) under palladium catalysis in the presence or absence of the supramolecular ligand **L** at 130 °C for one hour in pure toluene solvent (Scheme 2). In all cases, the reactions performed in the presence of the supramolecular ligand **L** led to yields of olefinated products **3** that were higher

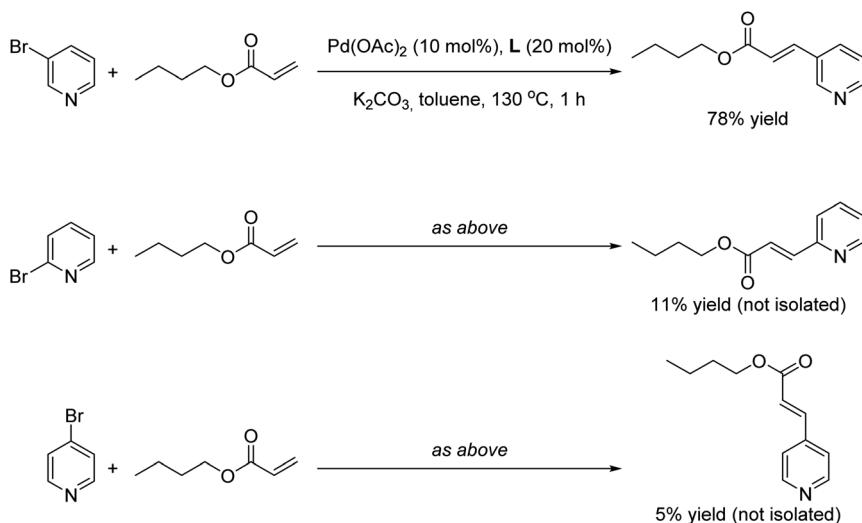

**Scheme 2** Influence of the supramolecular ligand **L** in the palladium-catalyzed Mizoroki–Heck cross-coupling between 3-bromopyridine and olefin derivatives.

than those observed for the reactions carried out in its absence. For instance, the products **3b** and **3c** resulting from employing methyl acrylate (**2b**) and *tert*-butylacrylate (**2c**), respectively, were formed in 50–59% yield in the presence of **L**, whereas only trace amounts (<5%) formed in the absence of **L**. Similarly, in the case of benzyl acrylate (**2d**), the supramolecular palladium catalyst afforded the corresponding product **3d** in 87% yield, whilst only traces were detected in the non-supramolecular version after one hour. Olefins with a more electron donating character such as styrenes underwent a similar trend as observed for acrylates. For example, non-functionalized styrene (**2e**) reacted with 3-bromopyridine (**1**) under supramolecular palladium catalysis leading to product **3e** in a virtually quantitative yield (95%). On the other hand, the catalysis performed in the absence of **L** led to a drop in the yield of product **3e** to 15%. Styrene derivatives with electronically different substitution patterns such as methoxy and fluoride are also compatible with this supramolecular palladium catalysis affording the corresponding products **3f** and **3g** in 89% and 43% yields, respectively. The reactions carried out without the supramolecular ligand **L** led to 50% yield of **3f** and 13% yield of **3g**. Such supramolecular effect was also observed when employing *N,N*-dimethylacrylamide (**2h**), which afforded the olefinated product **3h** in 26% yield, whereas an even lower 7% yield of **3h** was obtained in the absence of **L**. The supramolecular effect was also observed with methyl methacrylate as the olefin partner, which gave rise to the trisubstituted olefin **3i** in 50% yield whilst only 20% of **3i** was formed without the supramolecular ligand **L**. No reactivity was observed for the challenging, unfunctionalized acrylamide.

Finally we wondered whether our supramolecular palladium-catalyzed Mizoroki–Heck reactions displayed substrate selectivity to some extent. For this purpose, 2- and 4-bromopyridine were employed as substrates under the optimal reaction conditions in the presence of butyl acrylate as coupling partner (Scheme 3). Whereas the reaction with 3-bromopyridine afforded 78% yield of the

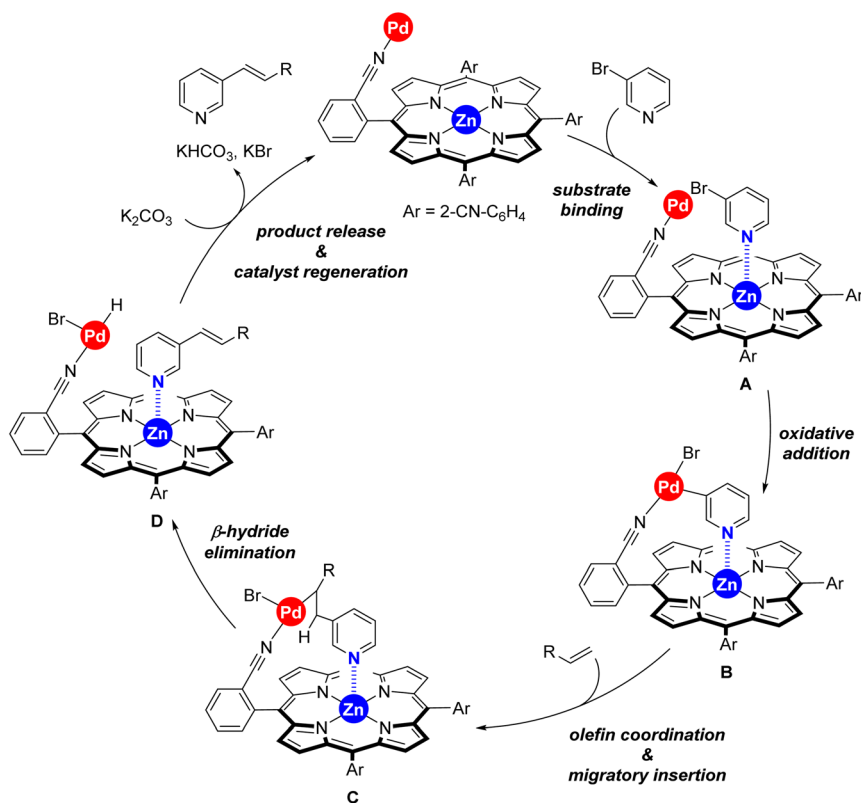

**Scheme 3** Influence of the regioisomer bromopyridine substrate in the final outcome of the supramolecular palladium-catalyzed Mizoroki–Heck cross-coupling reaction.

corresponding product (Scheme 3, top), the yields of the olefinated products derived from the other regioisomers did not surpass 11% yield in the best case (Scheme 3, middle and bottom). As such, these observations indicate that the supramolecular palladium catalyst is more adapted for reaction with the *meta* isomer over the *ortho* or *para* isomers. Such observation is reminiscent of our previous findings on supramolecular palladium-catalyzed Suzuki–Miyaura reactions,<sup>10</sup> but in the present case they are found at relatively higher reaction temperatures and short reaction times.

Taking into account the well-known reaction mechanism for palladium-catalyzed Mizoroki–Heck reactions and all the above discussed observations, we propose the catalytic cycle shown in Scheme 4 for our supramolecular palladium catalyst.<sup>11,17</sup> After initial *in situ* formation of palladium(0),<sup>18</sup> the peripheral nitrile groups in the supramolecular ligand **L** coordinate to palladium whilst the 3-bromopyridine substrate binds to the zinc–porphyrin molecular recognition site of **L** (formation of species **A**). Oxidative addition at palladium leads to the intermediate **B** followed by olefin coordination and migratory insertion towards species **C**. A final  $\beta$ -hydride elimination leads to the olefinated product **3** whereas

**Scheme 4** Postulated reaction mechanism for the supramolecular palladium-catalyzed Mizoroki–Heck cross-coupling reaction between 3-bromopyridine and terminal olefins exploiting remote, kinetically labile Zn $\cdots$ N weak interactions between the catalyst and the substrate.

the base mediates reductive elimination at palladium, thus regenerating the active palladium(0) species. At this stage, we cannot determine whether catalyst regeneration occurs with the substrate or with the product binding to the molecular recognition site.<sup>19</sup> This mechanistic proposal explains also the substrate selectivity encountered between the three different regioisomeric bromopyridine derivatives discussed in Scheme 3.

## Conclusions

In summary, we have disclosed a supramolecular palladium-catalyzed Mizoroki–Heck cross-coupling reaction in which the reactivity is enhanced thanks to remote Zn⋯N interactions between the molecular recognition site in the catalyst and the 3-bromopyridine substrate. The increased reactivity of the supramolecular catalyst is evidenced in relatively short reaction times (up to one hour) and high reaction temperatures (130 °C), which is rare for supramolecular catalysts that feature substrate-recognition properties. In addition, we managed to identify that the presence of small amounts of highly polar DMF solvent are still compatible for observing such supramolecular effect, which is important for the development of future supramolecular catalysts that would require different polarity media. By means of in-depth NMR studies, this work also discloses that the kinetically labile Zn⋯N interaction between the catalyst and the substrate is compatible with potentially coordinating groups encountered in other reagents such as the ester groups from acrylate coupling partners. This supramolecular catalysis was also tolerant to typically less reactive olefins such as styrene derivatives and a certain degree of substrate selectivity was identified by evaluating all the three regioisomeric bromopyridines. We anticipate that these findings might be of interest to develop new supramolecular catalysts for challenging transformations.

## Experimental

The supramolecular ligand **L** was prepared according to a previous report.<sup>10</sup>

### General procedure for the supramolecular catalysis

An overnight-dried Schlenk tube was filled, under an argon atmosphere, with 3-bromopyridine **1** (7.9 mg, 4.8 μL, 0.05 mmol, 1 equiv.), the corresponding terminal olefin coupling partner (0.15 mmol, 3 equiv.), potassium carbonate (20.7 mg, 0.15 mmol, 3 equiv.), the supramolecular ligand **L** (7.8 mg, 0.01 mmol, 0.2 equiv.), Pd(OAc)<sub>2</sub> (1.12 mg, 0.005 mmol, 0.1 equiv.) and toluene (1 mL). After 5 min stirring at room temperature the mixture was placed in a preheated oil bath at 130 °C and stirred for one hour. The reaction mixture was cooled down to room temperature and further analyzed by GC-MS.

### General procedure for the synthesis and characterization of the products resulting from the catalysis

An overnight-dried Schlenk tube was filled, under an argon atmosphere, with 3-bromopyridine **1** (7.9 mg, 4.8 μL, 0.05 mmol, 1 equiv.), the corresponding terminal olefin coupling partner (0.15 mmol, 3 equiv.), potassium carbonate (20.7 mg, 0.15 mmol, 3 equiv.), Pd(OAc)<sub>2</sub> (1.12 mg, 0.005 mmol, 0.1 equiv.) and

*N,N*-dimethylformamide (1 mL). After 5 min stirring at room temperature the mixture was placed in a preheated oil bath at 130 °C and stirred for 24 hours. The reaction mixture was cooled down to room temperature and the solvents evaporated under vacuum followed by purification by column chromatography (SiO<sub>2</sub>, ethyl acetate/pentane) to afford the corresponding olefinated products 3.

## Author contributions

N. A. designed and performed all the experiments as well as all data analysis. N. A. and R. G.-D. discussed the results and wrote the manuscript.
