Applying psoralen interstrand crosslinks for the photoactivation of nucleic acids is a new concept. To find chromophores that can efficiently stimulate crosslink repair we screened several pyrenes and appended them to peptide nucleic acids for their site-selective addressing. Even though pyrenes conjugated to uracil revealed desirable spectroscopic properties they were not effective in crosslink reversal. In contrast, bare pyrenes are well suitable for crosslink repair with 350 nm light showing an uncaging efficiency similar to classical photocaging groups.

Introduction

Psoralen is a plant natural product that can damage nucleic acids in a light-dependent manner.¹ Both DNA and double-stranded RNA can be interstrand crosslinked *via* two consecutive [2 + 2] cycloadditions of the psoralen moiety with neighboring pyrimidine bases in particular on 5'-d(TA) and 5'-r(UA) motifs (Scheme 1). Such crosslinked nucleic acids cannot be unwound, their secondary structure is frozen and their biological activity is often completely blocked. Since psoralen interstrand crosslinks are difficult to repair *in vivo*² they are highly mutagenic and useful as warheads³ in antisense and antigene applications. We consider site-selective psoralen-crosslinks as useful tools to manipulate gene functions with light due to the

strong impact of a single crosslink on the biological function of a nucleic acid. Along those lines, we demonstrated that psoralen crosslinks can be reversed in a photolyase-like manner by steering an external photoelectron transfer (PET) chromophore to the crosslink.⁴ Reversal occurs in a two-step mechanism involving formation of one unmodified strand and one strand carrying a psoralen monoadduct. The psoralen monoadduct can be subsequently removed in a light-dependent way either by direct absorption or by a second electron transfer reaction.⁴ For many biological functions the freezing of the structure limits the function. Thus the function is already restored upon breakdown of the crosslink into the monoadduct. A typical example for this is the photocontrol of transcription/translation from a psoralen-crosslinked luciferase gene as we have recently achieved.⁵ Even though the crosslink is not fully removed the gene activity was readily activated with light. Since no residual luciferase activity above the background was observed for the crosslinked gene, very high photoactivation efficiencies (≥ 500 fold) were obtained.⁵ However, application in biology requires more suitable chromophores than the phenothiazine used in our initial study⁴ in particular with respect to the photo-activation wavelength and efficiency ($\epsilon\phi$). The method could also benefit from an orthogonally excitable or a more photostable chromophore than 1-amino-pyrene.⁵ Thus, we have screened several pyrene chromophores with strong absorbance (ϵ) between 330 and 450 nm which we report here.

Scheme 1 General scheme for the caging of nucleic acids with psoralen (AMT 1). The interstrand crosslink can be removed in a photoelectron-dependent manner by addressing a suitable chromophore in proximity to the crosslink applying a peptide nucleic acid (PNA),⁴ for instance.

Results and discussion

Reversal of the crosslink requires the injection of a photoelectron into the crosslink. We anticipate that electron transfer occurs to the 5,6-alkylated thymidine moieties of the crosslink.⁶ From excess electron transfer studies in DNA⁷ several

electron donors are known to inject electrons readily into thymidine, 5,6-dihydrothymidine and thymine oxetanes.⁸ All such donors are possible candidates for the repair of the psoralen crosslink too. The class of pyrene chromophores is particularly interesting because pyrenes exhibit very strong extinction coefficients (ϵ) and have been used already in the context of DNA and RNA as probes to monitor hybridization, sequence, or to inject electrons.⁹ Beside the bare pyrene chromophore, derivatized pyrenes with interesting properties have been described, in particular those that are conjugated to uracil.¹⁰ Attachment of the pyrene directly at its 1-position to the C5-carbon of uracil results in a chromophore with a slightly red-shifted absorbance spectrum that has been used for the study of excess electron transfer through the nucleobase stack. Insertion of an additional two-atom ethynyl bridge between the pyrene and the uracil moieties even further shifts the absorption spectra to the red and strongly increases the excitation coefficient ($\lambda_{\max} = 392 \text{ nm}$ with $40 \text{ mM}^{-1} \text{ cm}^{-1}$).¹¹ If such chromophores could efficiently transfer an electron to the crosslink and stimulate the breakdown of the crosslink the application of the method may become possible at a much more suitable wavelength for cellular experiments (350–450 nm). For this reason we have synthesized peptide nucleic acids carrying a C-terminal modification with either a bare pyrene or a pyrene conjugated to uracil including or lacking an ethynyl bridge.

Peptide nucleic acids (PNA) are nucleic acid analogs that contain a non-charged, highly flexible pseudo-peptidic aminoethylglycine (aeg) instead of the natural phosphodiester backbone.¹² The canonical nucleobases are attached *via* acetic acid moieties to the backbone. PNAs bind DNA and RNA with very high free energy gain and strong mismatch discrimination. Due to the lack of charge they invade into dsDNA, displace one strand and bind the other *via* the Watson–Crick sites. We wanted to make use of the invasion-driven antigene binding mode in order to bring the chromophore, in a sequence-addressable way, as close as possible to the crosslink.⁴

We designed the PNA probes such that they approach the crosslinked 5'-d(TA) site from the 3'-end (Scheme 2). This may potentially allow for base-pairing of the orphan adenosine at the crosslink site with the pyrene-modified uracil. For this the chromophores had to be installed at the C-terminus of the PNA. To circumvent the synthesis of complete Fmoc-protected aeg building blocks for each pyrene derivative we decided to modify an L-diaminopropionic acid (Dpr) with various pyrene acetic acids directly on the solid support instead. The installation of the pyrene moieties at the C-terminus *via* the Dpr building block results in a "PNA-like" building block, however not in a conventional aeg PNA building block but rather in a *S*- γ -modified aeg PNA building block (Scheme 3). Since *S*- γ -modified PNAs are well studied and are known for the positive effects of the γ -modification on the PNA/DNA duplex stability,¹³ we consider the uracil-pyrene derivatives as being delivered in a backbone context that would potentially support or at least not obstruct the base pairing with the orphan adenosine.

Scheme 2 Invasion strategy for the sequence-specific addressing of the pyrene chromophores in proximity to the crosslink in a self-paired, crosslinked 24 + 24 nt DNA (12). The uracil-conjugated pyrenes could potentially base-pair to the orphan adenosine at the crosslink site. PNA is shown in grey with small letters.

To attach the bare pyrene group to the PNA, commercially available 1-acetyl pyrene 2 was activated as the pentafluorophenol ester 3 (Scheme 3). In order to introduce the pyrene chromophore at the C5-carbon of uracil, we first synthesized 5-iodo-uridine-*N*-acetic acid 4 in two steps similarly to literature protocols for similar compounds.¹⁴ The direct attachment of the chromophore was achieved by a Pd-catalyzed Suzuki cross-coupling with commercially available pyrene-1-boronic acid 5.¹⁵ The intermediate acid was directly transformed into the pentafluorophenylester 6 by transesterification with pentafluorophenol trifluoroacetate in DCM-pyridine for solid phase PNA synthesis. The attachment *via* an ethynyl bridge was achieved by Sonogashira coupling with commercially available 1-ethynyl-pyrene 7.¹¹ The intermediate acid was activated as the respective pentafluorophenylester 8. PNAs were synthesized from commercially available building blocks by applying

Scheme 3 Synthesis of the pyrene-modified peptide nucleic acids (PNA). (a) PfpOTFA, DCM–pyridine; (b) Pd(PPh₃)₄, NaOH, THF–water reflux; (c) PfpOTFA, DCM–pyridine; (d) Pd(PPh₃)₄, CuI, Hünig base, DMF, 80 °C; (e) PfpOTFA, DCM–pyridine; (f) 0.5% TFA in DCM–HFIP 2 : 1; (g) **3**, **6**, or **8**, Hünig base, DMF o.n.

the Fmoc/Bhoc strategy and HATU/HOAt activation protocols on TG-R^R Rink amide resin (NovaBiochem).¹⁶ The sequence of the PNAs was H-Lys–ctgctgcc–Dpr(β-pyrene)–Lys–Lys–NH. Directly after coupling of the Fmoc–Dpr(Mtt)–OH building block, peptide synthesis was stopped for the introduction of the respective pyrene chromophore. For this, the Mtt group was removed selectively on the solid support by treatment with 0.5% TFA in HFIP–DCM 1 : 2. Then the pyrene

chromophores **3**, **6**, or **8** were coupled to the β-amino group of the Dpr building block respectively. Subsequently, PNA synthesis was continued by deprotection of the α-Fmoc protection group of the Dpr residue. Unfortunately, removal of the Mtt group was impossible at the end of the PNA synthesis because the Bhoc protection groups were unstable with Mtt removal. All PNAs were purified by HPLC and their integrity was confirmed by high-resolution mass spectrometry.

The comparison of the UV-spectra of the new pyrene-modified probes (**9–11**) and our previously reported phenothiazine-containing PNA clearly reveals the attractive absorption properties of the latter. All three chromophores absorb light at $\lambda \geq 350$ nm with substantial extinction coefficients. The bare pyrene chromophore attached to PNA **9** still exhibits the typical absorbance spectra with maxima at 334 nm (20 mM⁻¹ cm⁻¹) and 350 nm (29 mM⁻¹ cm⁻¹). Since the bands are very steep the bare pyrene hardly absorbs above 365 nm (≈ 2 mM⁻¹ cm⁻¹ at 365 nm). Even though the positions of the bands stay nearly unchanged, the pyrene absorption bands get broadened upon conjugation to the uracil base in PNA **10**. Hence, this PNA still has a significant absorbance at 365 nm (12 mM⁻¹ cm⁻¹). Further incorporation of the ethynyl bridge into PNA **11** gives an enormous red-shift of ≈ 60 nm and a strong increase in absorbance (Fig. 1).

We tested the PNAs for the opening of a short crosslinked double-stranded nucleic acid substrate basically as before.⁴ The substrate was obtained by crosslinking the partially self-pairing 24 nt oligomer 5'-d(pGGAACAGCAGCCTAGGCGAGCA GG) with aminomethyltrisoralen¹⁷ (**1**) as described before.⁴ The two PNA binding sites are directly located downstream of the 5'-TA crosslink site (italic) and allow for the positioning of the pyrene chromophore in closest proximity to the cross-linked site. For photoactivation, the crosslinked DNA species **12** was diluted in argon-saturated sodium phosphate buffer (100 mM NaCl, pH 7.0) to a final concentration of 1 μM. The respective PNA **9**, **10**, or **11** was added to a final concentration of 4 μM providing an excess of two equivalents of PNA per PNA binding site. The mixture was briefly heated to 70 °C, re-hybridized at 15 °C and was then irradiated at 15 °C using a

Fig. 1 UV absorbance spectra of synthesized PNAs **9**, **10**, and **11** that carry a pyrene or the phenothiazine⁴ moiety respectively.

fluorescence spectrometer under exact control of the wavelength and irradiation time. After various time points (0 to 80 min) aliquots (2.5 μ OD DNA) were taken out and subjected to denatured 15% polyacrylamide electrophoresis. In order to reduce the smearing effect caused by the strong binding of the PNA even in the presence of urea, 1.5% formaldehyde was added to the loading buffer and the samples were heated (90 $^{\circ}$ C) prior to loading on the gel. For densitometric analysis a series of known amounts of the starting material and the single-stranded 24 nt DNA product were loaded on the gel (Fig. 2).

Upon irradiation at 350 ± 20 nm PNA 9 carrying the bare pyrene chromophore quickly opens the crosslinked DNA in formation of the expected 24 nt single-stranded DNA product. From the densitometric analysis the half-life for the formation

of the single-stranded product was determined to be 5.4 ± 0.5 min and reached a plateau after formation of ≈ 1.4 μ OD (Fig. 2). In contrast, both PNAs 10 and 11 with the pyrene chromophore conjugated to uracil failed to reverse the crosslink significantly over the background reaction. For the ethynyl-bridged pyrene PNA 11 one could have expected a failure because this chromophore is incapable of injecting excess electrons into the nucleobase stack,¹⁸ a process that should be energetically very similar to the injection of an excess electron into the thymidine part of the crosslink.^{19,4,8b} From the injection energetics one would expect that at least 3 eV, or light with $\lambda \leq 410$ nm, are required: ≈ 2 eV for the reduction of the crosslink, ≥ 0.5 eV driving force to overcome the reorganizational energy and ≥ 0.5 eV for the oxidation of the charge donor.⁵ However, it is unclear why the uracil-conjugated pyrene chromophore in PNA 10 fails as it was demonstrated before that U-pyrene quickly undergoes charge separation ($U^- - pyr^+$) upon photoexcitation.⁹ By transient absorbance spectroscopy it was further shown that the excess electrons from the uridine base can travel into the nucleobase stack.^{15,20} However, it is difficult to assess from such spectroscopic experiments if the charge-separated state is long-lived enough to efficiently stimulate crosslink reversal or if a fast charge recombination will inhibit the repair reaction.

Compared to our previously reported phenothiazine-PNA (half-life ≈ 26 min at 330 ± 20 nm for the opening of the crosslinked DNA into the product and a monoadduct)⁴ the crosslink reversal with the bare pyrene is notably efficient, and shifted to a more suitable wavelength. Since photoactivation in biological but also non-biological settings is routinely performed with 365 nm light we repeated the irradiation experiment with the pyrene-PNA 9 at 365 ± 20 nm. Again we observed the formation of the desired single-stranded DNA product, however, at a reduced rate (half-life = 12.8 ± 1.2 min). The less efficient opening is in accordance with the lower extinction coefficient of pyrene at 365 nm compared to 350 nm.

In order to determine the photoactivation efficiency $\epsilon\phi$ we directly compared the formation of the single-stranded product with the liberation of cAMP from a dimethoxy-nitro-benzyl-caged (DMNB) precursor⁵ at 350 ± 20 nm under identical settings. From the reported value $\epsilon\phi = 600 \text{ M}^{-1} \text{ cm}^{-1}$ and the measured half-life for the formation of cAMP of 3.5 ± 0.2 min we can directly estimate $\epsilon\phi$ for the crosslink reversal by pyrene PNA 9 to be $\approx 400 \text{ M}^{-1} \text{ cm}^{-1}$. Thus, the reversal of a psoralen crosslink can be achieved with an efficiency that is reduced but comparable to that of the classical photocaging group DMNB. Since up to two pyrene-PNAs need to be taken into account the quantum yield can be estimated to be in the range of $\approx 1\%$.

Conclusions

In summary, we have established a bare pyrene as a chromophore that can photoactivate psoralen crosslinks with 350–365 nm light with an efficiency similar to that of the DMNB group. We further reported on a fast synthesis of PNA probes that were C-terminally modified with different PET

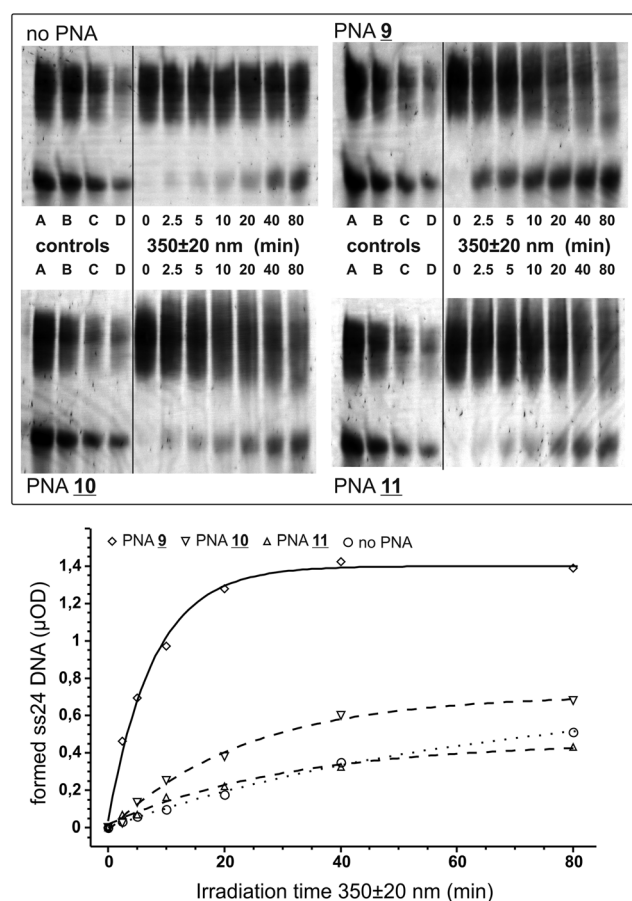

Fig. 2 Gel assay and kinetic analysis for the photoreversal of crosslinked DNA 12 with PNAs 9, 10, and 11, or in the absence of PNA at 350 ± 20 nm irradiation. Top: PAGE analysis of the photoreaction. As controls, known amounts (μ OD) of both xl24 DNA 12 (upper band) and the expected ss24 product (lower band) were loaded: A = 2.5 μ OD; B = 1.25 μ OD; C = 0.63 μ OD; D = 0.31 μ OD. Bottom: kinetic analysis of the formed 24 nt single-stranded DNA (lower band). Amounts (μ OD) of the formed ss24 product were determined by comparison with the mean gray values of reference DNA (controls A–D). Trend lines were obtained by fitting 1st-order kinetics. The half-life for the crosslink removal with PNA 9 (line) was determined to be 5.4 ± 0.5 min. The trend line for the PNA-free experiment is dotted.

chromophores including a bare pyrene and two uracil–pyrene conjugated chromophores. Why the latter two are incapable of reversing the crosslink remains elusive. However, they may be useful as hybridization probes or for the assembly of nano-materials.^{9,21} Similar strategies that mimic photolyase-like activity may also be useful to reverse other crosslinks.²²

Experimental section

Pentafluorophenyl 2-(pyren-1-yl)acetate (3)

1-Pyrene acetic acid **2** (112 mg, 0.43 mmol) was dissolved in dry DCM (30 mL), and pyridine (0.10 mL) and pentafluorophenol trifluoroacetate (0.1 mL) were added. After 2 h of stirring at r.t. DCM was removed, ethyl acetate (50 mL) was added and extracted with saturated NaHCO₃ (3 × 50 mL), brine, and 1% HCl (3 × 50 mL), and brine, and dried over sodium sulfate. The product was obtained as a faint yellow residue (180 mg, 0.42 mmol) and was used in PNA synthesis without further purification. TLC (ethyl acetate): *R_F* (product) = 0.91; *R_F* (free acid of product) = 0.05; ¹H-NMR (400.2 MHz, CDCl₃): δ = 4.59 (s, 2H; CH₂), 7.90–8.20 (m, 9H; pyrene CH); ¹³C-NMR (100.6 MHz, CDCl₃, ¹H uncoupled, not ¹⁹F uncoupled): δ = 38.4 (CH₂), 122.5 (CH), 124.6 (CF), 124.9 (CH), 125.1 (CF), 125.4 (CH), 125.6 (CH), 125.7 (C), 126.2 (CH), 127.3 (CH), 127.7 (CH), 128.3 (CH), 128.5 (CH), 129.5 (CF), 130.7 (CF), 131.2 (CF), 131.3 (CF), 167.5 (CO) ppm, CH could be discriminated from CF *via* ¹H/¹³C HSQC, HR-ESI-TOF-MS: 449.0571 expected for C₂₄H₁₁F₅O₂Na₁, 449.0573 found.

5-Iodo-uracil-N1-acetic acid (4)

5-Iodouracil (5 g, 21 mmol) was suspended in dry DMF (100 mL) under an inert atmosphere. 1-Bromo-methylacetate (2.1 mL, 21 mmol) and potassium carbonate (3.1 g, 22 mmol) were added and the mixture was stirred at r.t. for 14 h. The solvent was removed, water (150 mL) was added, and pH was adjusted to 7.0 with HCl. The precipitated product was separated on a funnel, washed with cold water (500 mL) and dried. The raw product (2 g, 6.45 mmol) was dissolved in THF (20 mL). Under stirring at 0 °C, LiOH (0.7 g, 29 mmol) in water (30 mL) was added and the mixture was stirred for 2 h. The solution was acidified (<pH 2.0) with HCl at 0 °C and the precipitate was filtered and was washed with ice-cold 0.1% HCl solution (2 × 50 mL) and dried to obtain 1.3 g (4.4 mmol) of product **4** as a white powder. TLC (ethyl acetate–MeOH 9 : 1 + 1% AcOH): *R_F* = 0.35; ¹H-NMR (600.13 MHz, D₆-DMSO): δ = 4.42 (s, 2H; CH₂); 8.22 (s, 1H; H-6); 11.78 (s, 1H; NH); 13.30 (s br, 1H; OH) ppm; ¹³C-NMR (150.9 MHz, D₆-DMSO): δ = 49.4 (CH₂); 68.9 (C-5); 151.1 (C-6); 151.6 (C-2); 162.0 (C-4); 170.2 (COOH) ppm; C–H connectivity was assigned *via* ¹H/¹³C-HSCQ; the N1-regioisomer was clearly assigned *via* ¹H/¹³C-HMBC; HR-ESI-TOF-MS: 296.9367 expected for C₆H₆I₁N₂O₄, 296.9363 found.

Pentafluorophenyl 2-(5-(pyren-1-yl)-uracyl)acetate (6)

5-Iodo-uracil-N1-acetic acid **4** (0.5 g, 1.7 mmol) and pyrene-1-boronic acid **5** (0.42 g, 1.7 mmol) were dissolved in THF

(20 mL) under an inert gas. Tetrakis(triphenylphosphane)-palladium(0) (200 mg = 10 mol%) and sodium hydroxide (1.36 g) in water (20 mL) were added. Methanol (20 mL) was added and the mixture was refluxed at 80 °C for 4 h and heated at 60 °C overnight. Solvents were removed, and the residue was distributed between water and chloroform, Pd was removed by filtration. The aqueous layer was extracted with chloroform (3 × 50 mL), acidified to pH < 2 (HCl) and the precipitated product was taken up in ethylacetate, washed with ammonium chloride (5%, 3 × 50 mL) and brine, and was dried over sodium sulphate to obtain 72 mg of the yellow raw product which was characterized by ¹H-NMR and high resolution mass analysis. The raw product (16 mg, 43 μmol) was dissolved in dry DCM (20 mL). Dry pyridine (0.1 mL) and pentafluorophenol trifluoroacetate (0.1 mL) were added. After 2 h of stirring at r.t. DCM was removed, ethyl acetate (50 mL) was added and extracted with saturated NaHCO₃ (3 × 50 mL), brine, 1% HCl (3 × 50 mL), and brine, and dried over sodium sulphate to obtain **6** as a yellow solid (10 mg, 19 μmol) that was used in PNA synthesis without further purification. TLC (ethylacetate): *R_F* (product) = 0.91; *R_F* (free acid of product) = 0.05; ¹H-NMR (250.1 MHz, D₆-DMSO): free acid: δ = 4.57 (s, 2H; CH₂); 7.92–8.35 (m, 10H; H-6, pyrene CH); 13.21 (s br, 1H; COOH); ¹³C NMR (101 MHz, D₆-DMSO): δ = 170.0 (COOH), 163.5 (C-4), 151.3 (C-2), 146.1 (CH, C-6), 131.1 (C), 131.0 (C), 130.7 (C), 129.8 (C), 129.2 (C), 128.6 (CH), 128.0 (CH), 127.7 (CH), 127.7 (CH), 126.8 (CH), 125.8 (CH), 125.6 (CH), 125.4 (C), 125.0 (CH), 124.3 (CH), 124.1 (C), 113.0 (C-5), 49.2 (CH₂); HR-ESI-TOF-MS: free acid: 369.0881 expected for C₂₂H₁₃N₂O₄, found 369.0876.

Pentafluorophenyl 2-(5-(pyren-1-ylethynyl)uracyl)acetate (8)

5-Iodo-uracil-N1-acetic acid **4** (0.5 g, 1.7 mmol), 1-ethynyl-pyrene **7** (0.4 g, 1.7 mmol), tetrakis(triphenyl phosphane)-palladium(0) (97 mg = 5 mol%), and copper(I)-iodide (32 mg = 10 mol%) were dissolved in dry DMF–Hünig base 10 : 1 (11 mL) under an inert atmosphere. The mixture was stirred overnight at room temperature. Then the mixture was heated to 80 °C for 4 h until a black precipitate was formed. Solvents were removed under high vacuum. The mixture was distributed between 1% NaOH–water and chloroform, the product was extracted into the aqueous 1% NaOH layer (3×), the combined aqueous layers were extracted with chloroform (3 × 50 mL), and then acidified to pH < 2 (HCl). The precipitate was taken up in ethyl acetate, washed with 0.1% HCl, brine, dried over sodium sulfate and reduced to dryness to obtain a yellow raw product (500 mg). The raw product was suspended in DCM (20 mL). Dry pyridine (1 mL) and pentafluorophenol trifluoroacetate (0.8 mL) were added. After 2 h solvents were removed, ethyl acetate (50 mL) was added and extracted with saturated NaHCO₃ (3 × 50 mL), brine, 1% HCl (3 × 50 mL), and brine, and dried over sodium sulfate. Silica gel (5 g) was added and the solvent was removed. The product was eluted from the silica gel with ethylacetate–hexane 1 : 1 (300 mL), the solvent was removed, the product was obtained as a yellow solid and was used in solid phase PNA synthesis without further purification. TLC (ethylacetate 100%): *R_F* (product) = 0.95; *R_F* (free

acid of product) = 0.05; $^1\text{H-NMR}$ (250.1 MHz): δ = 4.50 (s, 2H; CH_2); 8.06–8.63 (m, 10H; H-6, pyrene CH); 11.86 (NH) ppm; $^{13}\text{C-NMR}$ (101 MHz, $\text{D}_6\text{-DMSO}$): δ = 169.6 (COO), 162.3 (C4), 150.4 (C2), 149.7 (C6), 131.3 (C), 131.1 (C), 130.9 (C), 129.4 (C), 129.3 (C), 129.1 (CH), 129.1 (CH), 128.7 (CH), 127.6 (CH), 127.1 (CH), 126.3 (CH), 126.3 (CH), 126.0 (C), 125.3 (C), 125.2 (CH), 124.0 (CH), 123.7 (C), 98.8 (C5), 98.1 (ethinyl C), 91.6 (ethinyl C), 49.4 (CH_2); HR-ESI-TOF-MS: 583.0688 expected for $\text{C}_{30}\text{H}_{13}\text{F}_5\text{N}_2\text{O}_4\text{Na}_1$; 583.0687 found.

Solid phase PNA synthesis

Synthesis was performed for each PNA (9–11) on a 3 μmol scale on TG-RR Rink amide resin (Novabiochem) preloaded with Fmoc-Lys(Boc)-Lys(Boc) to 150 $\mu\text{mol g}^{-1}$ resin. Fmoc-Dpr(Mtt)-OH was coupled *via* the HBTU/HOBt activation protocol with 12 μmol Dpr and 11.5 μmol HBTU. After coupling of the Dpr residue, the Fmoc group was retained and the Mtt group was removed by dropping (1 mL min^{-1}) 15 mL 0.5% TFA in DCM-hexafluoro-2-propanol (2 : 1) over the resin. The resin was washed with DCM and NMP and prior to coupling of the pyrene chromophores, the resin was treated with 2% Hünig base-DMF. Pyrene chromophores were coupled by incubation of the resin with ≥ 12 μmol of either 3, 6, or 8 in 120 μL dry DMF overnight. Uncoupled amino groups were capped with acetic acid anhydride (8% in DMF-Hünig base 10 : 1). Synthesis of the PNA was continued after Fmoc removal of the Dpr residue following the HATU/HOAt protocol described earlier.^{4,16} The finished PNAs were released from the resin by dropping 5% triisopropylsilane in TFA (20 mL) over the resin. PNAs were purified on a preparative HPLC (Shimadzu LC20; linear gradients of eluent A (0.1% TFA-water) and eluent B (0.05% TFA in 90% acetonitrile) using a Macherey-Nagel Nucleodur column VP250/10 100-5 C18sec). PNA-sequences: PNA 9: H-Lys-ctgctgcc-Dpr(β -pyrene 3)-Lys-Lys-NH: UV: ϵ ($\text{mM}^{-1} \text{cm}^{-1}$) = 90 (260 nm), 21 (334 nm), 29 (350 nm), 2.0 (365 nm); MS: 775.8475 expected for $[\text{M} + 4\text{H}]^{4+}$: $\text{C}_{133}\text{H}_{178}\text{N}_{56}\text{O}_{34}$, found: 775.8490; PNA 10: H-Lys-ctgctgcc-Dpr(β -pyrene 6)-Lys-Lys-NH: UV: ϵ ($\text{mM}^{-1} \text{cm}^{-1}$) = 100 (260 nm), 26 (350 nm), 12 (365 nm); MS: 803.3504 expected for $[\text{M} + 4\text{H}]^{4+}$: $\text{C}_{137}\text{H}_{180}\text{N}_{58}\text{O}_{36}$, found: 803.3518; PNA 11: H-Lys-ctgctgcc-Dpr(β -pyrene 8)-Lys-Lys-NH: UV: ϵ ($\text{mM}^{-1} \text{cm}^{-1}$) = 100 (260 nm), 20 (365 nm), 36 (400 nm), 25 (430 nm); MS: 809.3504 expected for $[\text{M} + 4\text{H}]^{4+}$: $\text{C}_{137}\text{H}_{180}\text{N}_{58}\text{O}_{36}$, found: 809.3513. Extinction coefficients used for PNA: t ($8.4 \text{ mM}^{-1} \text{ cm}^{-1}$), a ($15.2 \text{ mM}^{-1} \text{ cm}^{-1}$), c ($7.05 \text{ mM}^{-1} \text{ cm}^{-1}$), g ($12.0 \text{ mM}^{-1} \text{ cm}^{-1}$).

Synthesis of the 24 + 24 nt crosslinked DNA

The self-pairing 24 nt ssDNA (Microsynth, Switzerland, HPLC purified, 5'-d(pGGAACAGCAGCCTAGCGAGCAGG), 15.5 OD, $\epsilon \approx 250 \text{ mM}^{-1} \text{ cm}^{-1}$, $\approx 62 \text{ nmol}$) was dissolved in 1.5 mL buffer (50 mM Tris/HCl, 10 mM MgCl_2 , 100 mM NaCl, 1 mM EDTA, 15 mM NaN_3 , pH 7.5) and purged with argon gas. Then aminomethyltrisoralen hydrochloride 1 (15 μL of 19 mM in DMSO, *ca.* 15 equiv. per duplex) was added. The solution was cooled down from 70 $^\circ\text{C}$ to 4 $^\circ\text{C}$ and irradiated at 4 $^\circ\text{C}$ with 340 \pm

10 nm light under stirring in a fluorimeter (75 W xenon arc lamp); after 3 h the same amount of AMT (15 μL) was added again and the irradiation was continued for further 3 h. The raw DNA was precipitated with ethanol/NaOAc dissolved in 180 μL gel loading buffer (1 \times TBE, 7 M urea, xylene cyanol and bromophenol blue), heated to 90 $^\circ\text{C}$ (3 min) and loaded on a 1 mm 15% denaturing (7 M urea) PAGE mini gel. The gel was run at 140 V in 1 \times TBE buffer for 120 min. The crosslinked species run a little bit faster than the xylene cyanol band while the single-stranded starting material runs slightly slower than the bromophenol blue band. The crosslinked species was cut out of the gel without staining or UV shadowing only by its relative position to the xylene cyanol band since 254 nm light reverses the crosslink. The crosslinked species 12 was extracted from the gel by the crush and soak method into pure water and was concentrated by ethanol-NaOAc precipitation. The final product was dissolved in 200 μL water resulting in an $\text{OD}_{260 \text{ nm}} = 13.5$ giving an overall yield of 2.7 OD [17%].

Irradiation experiments

Irradiation was performed on a QuantaMaster 7 (Photon Technology International) fluorescence spectrometer, equipped with excitation/emission monochromators, with a peltier element to control the sample temperature, and automatic shutters to control the irradiation time. The 24 nt crosslinked DNA substrate was diluted in 55 μL 10 mM sodium phosphate, 100 mM NaCl, and pH 7.0 buffer to a final $\text{OD}_{260 \text{ nm}} = 0.5$ ($\approx 1 \mu\text{M}$). Prior to irradiation, the respective PNAs 9–11 were obtained from 40–50 \times stock solutions to achieve a final $\text{OD}_{260 \text{ nm}} = 0.35\text{--}0.4$ ($\approx 4 \mu\text{M}$). At various time points (0, 2.5, 5.0, 10, 20, 40, and 80 min), samples (5.0 μL) were taken and subjected to a 15% (7.5 M urea) PAGE (19 : 1), 1 \times TBE. Prior to loading, 10 μL of loading buffer (TBE 1 \times , 7 M urea, 1.5 vol% 37% formaldehyde in water, cyanol blue dye) were added and then heated to 90 $^\circ\text{C}$ for 5 min. To determine the amounts of product and starting material densitometrically a dilution series of starting material 12 and the desired 24 nt ssDNA product was load on the gel (each 2.5 μOD , each 1.25 μOD , each 12.5 μOD , and each 0.31 μOD). After running the gel in TBE 1 \times , the gel was stained with SybrGold (Invitrogen) for 10 min in 1 \times TBE-acetic acid pH 7.8. The gel was documented on a gel Laser scanner (Fujifilm FLA 5100).

Acknowledgements

We thank the DFG (STA 1053/3-1), the Fonds der Chemischen Industrie and the University of Tübingen for generous financial support.
