Stable porphyrin Zr and Hf metal–organic frameworks featuring 2.5 nm cages: high surface areas, SCSC transformations and catalyses†

Jun Zheng,^{ab} Mingyan Wu,^{*a} Feilong Jiang,^a Weiping Su^{*a} and Maochun Hong^a

Two isostructural porphyrin Zr and Hf metal–organic frameworks (FJI-H6 and FJI-H7) are rationally synthesized, and are constructed from 2.5 nm cubic cages. Notably, they both possess high water and chemical stability and can undergo single-crystal to single-crystal transformations to embed Cu²⁺ ions into the open porphyrin rings. FJI-H6 has a high BET surface area of 5033 m² g⁻¹. Additionally, they exhibit promising catalytic abilities to convert CO₂ and epoxides into cyclic carbonates at ambient conditions.

Owing to their high surface area, permanent porosity and tunable pores, metal–organic frameworks (MOFs) have been used for catalysis,¹ gas separation and storage,² and drug delivery.³ Nonetheless, one big obstacle to the practical applications of MOFs is their stability, which includes water and chemical stability. To target stable MOFs, one effective method is the use of high-valence metal ions such as Fe³⁺, Al³⁺, Cr³⁺, Zr⁴⁺ and Hf⁴⁺ ions as the metal nodes.⁴ Compared with the traditional Cu²⁺, Zn²⁺ and Co²⁺ ions,⁵ the aforementioned trivalent or tetravalent metal ions will form stronger bonds with carboxylate groups according to the theory of hard and soft acids and bases. Therefore, the stability of the obtained frameworks will be strengthened. Furthermore, these high-valence metal ions tend to form highly connected inorganic clusters *via* the OH⁻ and/or O²⁻ bridges, which also significantly contributes to the stability of the frameworks. As for the Zr⁴⁺ ion, it prefers to form the classical 12-connected Zr₆O₄(OH)₄ node. When assembled with linear carboxylate ligands, 3D fcu frameworks with ordered cubic cages (known as the UiO series) can be obtained.⁶ These kinds of Zr-based MOF often have high water and chemical stability, and can even serve as water adsorbents.⁷ Up to now, extensive investigation has been carried out to tune the porosity of the UiO series of Zr-MOFs by selectively removing organic linkers⁸ or by functionalizing the ligands (by pre-modification or post-synthetic

methods).⁹ However, there are several examples based on the assembly of Zr₆O₄(OH)₄ clusters with polycarboxylic ligands such as planar tetracarboxylic acids.^{7b,10} In addition, compared with Zr-based MOFs, Hf-based MOFs are also rare.^{6f,11} Herein, we present two ultra-stable metal–organic frameworks ([Zr₆O₄(OH)₄(H₂TBPP)₃]_n·(solvent)_x) (FJI-H6) and ([Hf₆O₄(OH)₄(H₂TBPP)₃]_n·(solvent)_x) (FJI-H7), which are isostructural and both constructed from M₆O₄(OH)₄(CO₂)₁₂ nodes (M = Zr, Hf) and porphyrin tetracarboxylic ligands (H₂TBPP = 4',4''',4''''',4''''''-(porphyrin-5,10,15,20-tetrayl)tetrakis([1,1'-biphenyl]-4-carboxylic acid)). As expected, both FJI-H6 and FJI-H7 have high water and chemical stability and can undergo a single-crystal-to-single-crystal (SCSC) transformation to embed Cu²⁺ ions into the open porphyrin rings. Interestingly, they both feature 2.5 nm cages. Notably, FJI-H6 has a high BET surface area of 5033 m² g⁻¹.

Results and discussion

Syntheses and structures of porphyrin Zr and Hf MOFs

Reaction of H₂TBPP with ZrCl₄ or HfCl₄ modulated by benzoic acid gives rise to dark red crystals of FJI-H6 or FJI-H7. Single crystal X-ray structural analysis shows that FJI-H6 and FJI-H7 are isostructural.¹² Therefore, we chose FJI-H6 as the example in the following discussion. FJI-H6 crystallizes in the high symmetry space group *Pm* $\bar{3}$ *m*. In the Zr₆O₄(OH)₄ cluster, six equivalent Zr⁴⁺ ions are in a square-antiprismatic O₈ coordination environment and form a regular octahedron. In this Zr₆ octahedron, the eight triangular faces are alternatively capped by four μ_3 -OH⁻ and four μ_3 -O²⁻ groups. Additionally, the twelve edges of the Zr₆ octahedron are bridged by twelve carboxylate groups from twelve unique H₂TBPP ligands. At the same time, each H₂TBPP ligand, in which the peripheral four phenyl rings are coplanar with the inner porphyrin rings, links four independent Zr₆O₄(OH)₄ clusters. Thus, a rarely seen (4,12)-connected ftw framework can be acquired.^{10a,11b,13} FJI-H6 has two

† Electronic supplementary information (ESI) available: General experimental, syntheses and characterization of the complexes mentioned in the manuscript, details of the single crystal diffraction experiments, PXRD, TG and additional figures. CCDC 1043280, 1043281, 1043914 and 1043915. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/c5sc00213c

kinds of polyhedral cages, *i.e.* a small octahedral cage and a large cubic cage. As seen in Fig. 1, the octahedral cage is constructed from two $Zr_6O_4(OH)_4$ clusters and four H_2TBPP ligands, with a cavity diameter of *ca.* 1.5 nm. However, the cubic cage consists of eight $Zr_6O_4(OH)_4$ clusters as the vertices and six H_2TBPP ligands as the sides. Significantly, the diameter of the cubic cage is approximately 2.5 nm, which is larger than that in PCN-221 (2.0 nm).^{11b} Accordingly, the available volume is 15 000 Å³. Additionally, the window of the cubic cage is 1.2 nm × 2.0 nm, which allows large organic molecules to freely get in and out.

Gas adsorption experiments and stability tests

Calculation by PLATON software¹⁴ reveals that in **FJI-H6** the free volume is up to 78.6%. For **FJI-H6** the permanent porosity is confirmed by an N₂ adsorption isotherm measured at 77 K. The sample exchanged with acetone exhibits a reversible type I isotherm and has a saturated uptake of 1346 cm³ g⁻¹ at 1 atm (Fig. 2). When pre-treated with 8 M HCl, the value of the N₂ adsorption slightly increases to 1393 cm³ g⁻¹, which indicates that **FJI-H6** is stable with respect to the acid. From the above data, the calculated BET surface area of the sample exchanged with acetone is up to 5007 m² g⁻¹ (5033 m² g⁻¹ for the sample pre-treated with 8 M HCl), which is much larger than those of PCN-222(Fe) (2200 m² g⁻¹),^{4b} NU-1000 (2320 m² g⁻¹),¹⁵

Fig. 1 (a) The large cubic cage constructed from six porphyrin ligands and eight $Zr_6O_4(OH)_4$ clusters. (b) The small octahedral cage constructed from four porphyrin ligands and two $Zr_6O_4(OH)_4$ clusters. (c) Packing of the two kinds of cages.

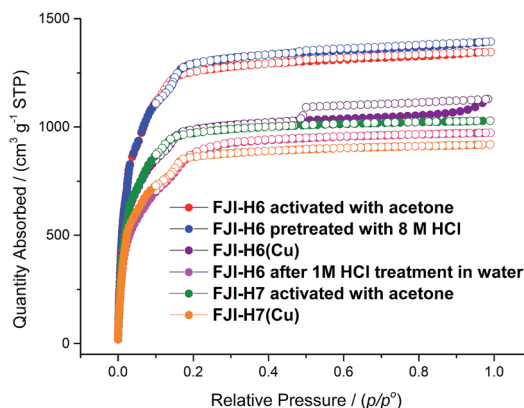

Fig. 2 Experimental N₂ adsorption isotherms for **FJI-H6**, **FJI-H6(Cu)**, **FJI-H7** and **FJI-H7(Cu)**.

PCN-223(Fe) (1600 m² g⁻¹),^{10c} PCN-94 (3377 m² g⁻¹),^{10b} NU-1100 (4020 m² g⁻¹)^{10a} and PCN-229 (4619 m² g⁻¹),¹³ but less than those of the just reported NU-1103 (5646 m² g⁻¹) and NU-1104 (5290 m² g⁻¹).^{10e} In addition, **FJI-H6** also has a high total pore volume of 2.16 cm³ g⁻¹. The experimental BET surface area and pore volume are consistent with theoretical values calculated by Poreblazer¹⁶ (accessible surface area: 4695 m² g⁻¹; pore volume: 2.06 cm³ g⁻¹),¹⁴ which demonstrates that the sample is fully activated. Additionally, **FJI-H6** also shows good capacity for H₂ storage. The H₂ uptake reaches 172 cm³ g⁻¹ (1.54 wt%) at 1 atm and 77 K, and 108 cm³ g⁻¹ (0.94 wt%) at 87 K and 1 atm. Moreover, the adsorption heat of H₂ calculated by the Clausius–Clapeyron equation is 6.54 kJ mol⁻¹ at zero coverage and decreases slowly with increasing H₂ loading. These values are comparable to those of famous MOF materials, such as HKUST-1 (6.6 kJ mol⁻¹),¹⁷ MOF-5 (5.2 kJ mol⁻¹),¹⁷ and NOTT-122 (6.0 kJ mol⁻¹).¹⁸ As for **FJI-H7** the sample exchanged with acetone also exhibits a reversible type I isotherm and has a saturated uptake of 1029 cm³ g⁻¹ at 1 atm. From the above data, the calculated BET surface area of **FJI-H7** is up to 3831 m² g⁻¹, which is among the highest reported for Hf-based MOFs.¹¹

Since the $Zr_6O_4(OH)_4$ and $Hf_6O_4(OH)_4$ clusters are both highly connected with twelve carboxylate groups, **FJI-H6** and **FJI-H7** are expected to have a high stability. To test their stabilities, we immersed a microcrystalline sample of **FJI-H6** or **FJI-H7** into water with various pH values for 24 h (see Fig. S2†). The PXRD patterns of the resulting samples match well with the simulated ones, which suggests that **FJI-H6** and **FJI-H7** retain their crystallinity. In particular, **FJI-H6** has high stability in acid. As seen in Fig. 2, the curves and the adsorption values for the sample treated with 8 M HCl do not deviate much from those of the untreated sample.

Incorporating Cu²⁺ ions into the open porphyrin rings *via* SCSC transformations

Considering that in both **FJI-H6** and **FJI-H7** two nitrogen atoms of the porphyrin ring are not deprotonated, we attempted to introduce a second kind of metal ion into the framework. Immersing single-crystals of **FJI-H6** or **FJI-H7** into a solution of 0.5 M Cu(NO₃)₂ in *N,N*-dimethyl formamide (DMF) at 85 °C for

72 h results in metallated **FJI-H6(Cu)** or **FJI-H7(Cu)**. As anticipated, single crystal X-ray structural analysis definitively shows that in both **FJI-H6** and **FJI-H7** the Cu^{2+} ions have been embedded in the porphyrin rings. The Cu^{2+} ion is in a square planar N4 coordination environment with two axial sites exposed, which is typical for divalent metal ions in metal-porphyrin complexes.¹⁹ We believe that, although there are several examples of exchanging metal ions in porphyrin MOFs, this is the first observation of incorporating metal ions into open porphyrin rings *via* SCSC transformations in porphyrin MOFs. N_2 adsorption measurements at 77 K for **FJI-H6(Cu)** also show a type I isotherm. At 1 atm, **FJI-H6(Cu)** has the maximum N_2 adsorption of $1128 \text{ cm}^3 \text{ g}^{-1}$, which is smaller than that of **FJI-H6**. Accordingly, the BET surface area of **FJI-H6(Cu)** is reduced to $3731 \text{ m}^2 \text{ g}^{-1}$. Similarly, the maximum N_2 adsorption and BET surface area of **FJI-H7(Cu)** ($918 \text{ cm}^3 \text{ g}^{-1}$ and $3195 \text{ m}^2 \text{ g}^{-1}$, respectively) are also lower than those of **FJI-H7**. The reason may be ascribed to the introduction of Cu^{2+} ions, which can slightly diminish the surface area.

Cycloaddition reactions of CO_2 with epoxides

Recently, owing to global warming, efficient CO_2 capture and storage is urgently needed to reduce CO_2 emissions before scientists find a practical clean energy. If we can convert this abundant inorganic waste into usable organic chemicals utilizing reasonable reactions at ambient conditions, the above problem can be perfectly solved. One practical method is the synthesis of cyclic carbonates from CO_2 and epoxides, which have extensive applications as degreasers, polar aprotic solvents and electrolytes in lithium ion batteries. Though many catalysts have been explored for the above reaction, metalloporphyrins show relatively high catalytic activity.²⁰ Hence, we have evaluated **FJI-H6**, **FJI-H6(Cu)**, **FJI-H7** and **FJI-H7(Cu)** as heterogeneous catalysts for the cycloaddition reaction of CO_2 with epoxides (Scheme 1). Typically, 25.5 mmol 3-chloropropylene oxide, 0.51 mmol (2.0 mol%) tetrabutylammonium bromide and 0.051 mmol (0.2 mol%) catalyst were added to a thick-walled glass tube with a stirring bar. The tube was placed under vacuum and then purged with CO_2 . The above cycle was repeated three times. Finally, the pressure of CO_2 was set as 1 atm. The mixture was stirred at 25°C for 60 hours. Analysis of the resulting solution by gas chromatography indicated that 52.6%, 61.8%, 64% and 66.5% of the epoxide was converted into the cyclic carbonate for **FJI-H6**, **FJI-H6(Cu)**, **FJI-H7** and **FJI-H7(Cu)**, respectively. Though the yields are not very high compared with homogeneous catalysts, it is nevertheless promising considering the low temperature and pressure.

Scheme 1 Cycloaddition reactions of CO_2 with epoxide catalyzed by **FJI-H6(Cu)**, **FJI-H7** and **FJI-H7(Cu)**.

Compared with **FJI-H6** or **FJI-H7**, **FJI-H6(Cu)** or **FJI-H7(Cu)** has a higher catalytic ability. The reason may be that, as a Lewis catalytic site, the embedded $\text{Cu}(\text{II})$ ion in the porphyrin ring contributes to some extent. At the same time, the Hf-based MOFs **FJI-H7** and **FJI-H7(Cu)** have higher catalytic abilities than the corresponding Zr-based MOFs **FJI-H6** and **FJI-H6(Cu)**, respectively since the Hf ion is more oxophilic than the Zr ion and acts as a stronger Lewis acid. Additionally, the PXRD patterns of **FJI-H6(Cu)**, **FJI-H7** and **FJI-H7(Cu)** after catalyses are in good agreement with the simulated ones (see Fig. S2†), which further demonstrates that they all retain their framework. However, it is a pity that **FJI-H6** lost its crystallinity during the catalytic process.

Conclusions

In conclusion, we report the design and synthesis of two ultra-stable MOFs **FJI-H6** and **FJI-H7**, which both feature 2.5 nm cages. In particular, **FJI-H6** has a high BET surface area of $5033 \text{ m}^2 \text{ g}^{-1}$. Due to the high connectivity of the $\text{M}_6\text{O}_4(\text{OH})_4$ clusters ($\text{M} = \text{Zr}$ and Hf), **FJI-H6** and **FJI-H7** are stable in water with pH values ranging from 0 to 10. Interestingly, they can undergo a single-crystal to single-crystal transformation to embed Cu^{2+} ions into the porphyrin rings, which also indicates their high chemical stability. Additionally, preliminary catalysis evaluation shows that **FJI-H6(Cu)**, **FJI-H7** and **FJI-H7(Cu)** exhibit promising catalytic capacity for converting CO_2 and epoxides into cyclic carbonates at low temperature and pressure. Consequently, **FJI-H6**, **FJI-H7** and their derivatives may be applied in catalysis due to their high surface area, ultra-high stability and easy post-modification. Further research is ongoing.
