Small hybrid heteroaromatics: resourceful biological tools in cancer research

Vikrant Abbot,^a Poonam Sharma,^{ID}^a Saurabh Dhiman,^a Malleshappa N. Noolvi,^b Harun M. Patel^c and Varun Bhardwaj^{*a}

Nowadays, hybrid drugs containing two or more covalently linked known potential pharmacophores are designed to simultaneously modulate multiple targets of multifactorial diseases to overcome the side effects associated with a single drug. In this review, an overview of the design strategies employed by various scientists over the past 20 years has been presented. The overview includes the synthesis of different chemical structure-based anticancer hybrids using molecular hybridization techniques. To tackle one of the world's most devastating diseases such as cancer, researchers have exploited the molecular hybridization (MH) technique to synthesize different anticancer hybrids, which include hybrids based on azole, camptothecin, chalcone, pyrrolobenzodiazepine (PBD), coumarin, colchicine, platinum, and some miscellaneous structures. The selection of two or more moieties for generating the hybrid drug is generally aided by the observed (or anticipated) synergistic or additive pharmacological activities of each single moiety. This eventually leads to the identification of novel and better active chemical entities with a superior profile as compared to the parent moieties. In addition to the design strategies, this review also highlights the structure–activity relationship (SAR), mechanism of action, and key features of the synthesized anticancer hybrids.

1. Introduction

Cancer is a cell cycle disease characterized by rapid, uncontrolled, and pathological proliferation of abnormal cells. It is one of the most formidable diseases in the world.^{1,2} The most frequent forms of cancer are lung cancer, breast cancer, colorectal cancer, stomach cancer, and prostate cancer; among these, prostate cancer (male) and breast cancer (female)

Vikrant Abbot obtained his Bachelor's degree in Pharmacy from the Punjab Technical University in 2009. He started his professional career working as a Production Chemist at Comed Pharmaceuticals Ltd. Baddi for 2.5 years. Thereafter, he completed his Master's degree in Medicinal Chemistry from JUIT, Waknaghat in 2014. Then, he joined academics and is currently working as an

Assistant Professor at ISF College of Pharmacy, Moga, Punjab. His present research interests include design and synthesis of small molecules with anticancer and antimicrobial profiles.

Poonam Sharma obtained her Master's in Philosophy in 2003 with a gold medal and completed her PhD in chemistry in 2006 from Himachal Pradesh University (India). She was awarded a UGC project fellowship for her PhD research. She was also awarded the Fast Track Young Scientist research project by DST in 2010. Presently, she is working as an Assistant Professor at the Jaypee Univer-

sity of Information Technology, Waknaghat, Solan (India). Her research revolves around physicochemical drug interactions, thermodynamics, heterocyclic bioactive analogs and topical drug delivery.

represent 29% of all cancer cases.³ Over the past few years, various techniques such as surgery, chemotherapy, immunotherapy, and radiotherapy have been employed to cure cancer. Currently, cancer therapy involves pharmacological interventions targeted at some pathogenic pathway, mostly a particular biological pathway.⁴ With these advancements in the field of cancer therapy, problems still persist with the available anti-cancer drugs. Most of the drugs are incapable of overcoming the resistance mechanism involved in the primary and secondary cancer cells and are also unable to differentiate between normal cells and neoplastic cells. This led to the general belief that the drugs simultaneously modulating more than one target would have better therapeutic potential as compared to single target drugs.⁵ Thus, to simultaneously modulate more than one target and combat different types of cancer, multi-target drugs were generated by combining two or more known pharmacophores to form a new single drug (hybrid drug). A hybrid molecule may

be defined as a combination of two different and independently acting compounds that are covalently linked to form one hybrid compound, which leads to a pharmacological potency greater than the sum of each individual moiety's potencies. This approach of developing multi-target drugs has been termed as molecular hybridization (MH). The active compounds or pharmacophoric units are recognized and derived from known bioactive molecules.⁶ Hybrid anticancer drugs have remarkable advantages over the conventional anticancer drugs because of their improved pharmacodynamic profile. This new method is highly suitable for developing more potent molecules to simultaneously target more than one pathogenic mechanism.⁷ Molecular hybridization not only enhances the activity or selectivity but can also reduce adverse drug effects.^{8,9} Molecular hybridization is believed to be analogous to combination therapy with the exception that two drugs are covalently linked and available as a single entity.⁴

Saurabh Dhiman was born in 1990 in Himachal Pradesh, India. He obtained his Bachelor's degree from JUIT, Waknaghat in 2012. He continued his postgraduate studies with specialization in Medicinal Chemistry at the same university and worked in the field of hybrid compounds as anticancer and antimicrobial agents.

Harun M. Patel is currently associated with the department of Pharmaceutical Chemistry, R.C. Patel Institute of Pharmaceutical Education and Research, Shirpur Maharashtra, India. He has outstanding research and academic experience. He has more than 70 publications in reputed peer reviewed international journals. His key research interests are working in the field of QSAR,

docking study, virtual screening, synthesis of novel anticancer, anti-tubercular and antiepileptic drugs. He has two patents and three international books to his credit. He is a well recognized teacher in medicinal and pharmaceutical chemistry and is well known for his innovative teaching skills.

Dr. Malleshappa Noolvi obtained his B. Pharmacy degree from SETs College of Pharmacy, Karnataka in 1997. He completed his M. Pharmacy from Government College of Pharmacy, Bangalore in 1999. He was awarded PhD in Medicinal Chemistry from the Rajiv Gandhi University of Health and Sciences, Bangalore, India. He has twenty-seven international research publications. He has

successfully completed various research projects granted by the Department of Science and Technology, New Delhi. Currently, he is working as a Professor at the Shree Dhanvantary Pharmacy College and Shree Dhanvantary Pharmaceutical and Analytical Research Center, KIM, Surat, Gujarat.

Dr Varun Bhardwaj received his PhD in Pharmacy in 2014 under the supervision of Dr Poonam Sharma and Dr S. Chauhan from Jaypee University of Information Technology. He received his Master of Pharmacy degree under the supervision of Prof. Malleshappa N. Noolvi. He worked under two DST funded projects, with 25 publications in international peer reviewed journals. His research interest

includes design and synthesis of bioactive heterocycles, physico-chemical interactions, and nano/microparticulates, topical formulations especially against microbial infections and drug safety/efficacy profile.

The molecular hybridization strategy has been globally employed by scientists to concomitantly address more than one biological target in cancer treatment that has enabled some anticancer hybrids to reach clinical trials. For example, estramustine hybrid of estradiol and nitrogen mustard is under clinical trial for various solid cancers. Brentuximab (Adcetris®), which is an antibody–drug conjugate, is under clinical trials since 2010. Some other examples include linkage of trastuzumab emtansine-antibody trastuzumab (Herceptin) to the cytotoxic agent mertansine (DM1), under clinical trial in women with advanced HER2 positive breast cancer (EMILIA), and development of NO–Aspirin hybrid (NO–ASA) as a chemopreventive agent. NO–ASA–H₂S hybrid seemed to be a promising molecule to be developed as a drug since it inhibited the growth of 11 different types of human cancer cells in culture (Fig. 1).¹⁰ Along with molecular hybridization, fragment-based drug discovery also plays an important role in developing hybrid molecules. Using this approach, small chemical fragments are identified and combined together to produce a lead molecule having higher affinity.¹¹

In this review, various strategies and approaches that have been employed to design hybrid molecules have been discussed. In addition, the structure–activity relationship, mode of action, and key features of the molecules with an impact on biological evaluation have also been highlighted. The major hybrid molecules discussed herein include azoles,

camptothecins, chalcones, pyrrolobenzodiazepines (PBDs), coumarins, colchicines, platinum-based hybrids, and some miscellaneous hybrid molecules.

2. Azole-based hybrids

Azole is a class of five-membered nitrogen ring compounds containing at least one non-carbon atom, *i.e.* nitrogen, along with sulphur or oxygen. Diverse azole-based hybrid molecules have been developed with potential anticancer activity and discussed below:

After identifying the importance of 1,2,3-triazole compounds using click chemistry, Duan *et al.* synthesized novel 1,2,3-triazole–dithiocarbamate hybrids¹² and evaluated them against four human tumor cell lines: MGC-803, MCF-7, PC-3, and EC-109. Among the synthesized hybrids, compounds **1** and **2** exhibited broad-spectrum anticancer activity with the IC₅₀ values ranging from 0.73 to 11.63 and 0.49 to 12.45 μ M, respectively. These compounds were found to inhibit the proliferation of MGC-803 cells *via* programmed cell death and imposing the cell cycle at the G2/M phase (Fig. 2).

The two major subfamilies extracellular signal-regulated kinase (ERK) and c-Jun of mitogen-activated protein kinases (MAPKs) are the key molecules for regulating breast cancer cell lines. The signaling pathways mediated by the combretastatin scaffold can be used to generate agents that are useful in the

Fig. 1 Molecules in clinical trials.

Fig. 2 Novel hybrids of 1,2,3-triazole-dithiocarbamate.

treatment of breast cancer. This information led Kamal *et al.*¹³ to synthesize combretastatin-amidobenzothiazole hybrid molecules with potential anticancer activity. Among the synthesized hybrids, compound **3** showed significant activity against a breast cancer cell line (MCF-7). Structure-activity relationship (SAR) studies further revealed that compound **3** had no substitution in the benzene ring of benzothiazole, which resulted in its higher activity with the GI_{50} value ranging from 0.019 to 11 μ M (Fig. 3).

Imidazolium salt hybrids can induce G1 phase cycle cell arrest and cause apoptosis of tumor cells. The success of these hybrid molecules directed Liu *et al.* to synthesize dibenzo [*b,d*] furan-imidazole hybrid compounds; moreover, these compounds were assessed against human tumor cell lines.¹⁴ Among the synthesized compounds, compound **4** showed significant activity against all human tumor cell lines. SAR suggested that the linking of naphthylacyl or 4-methoxyphenacyl group at the third position of the imidazole ring

Features

Compound **3** showed anti cancer activity by cell cycle arrest at G2/M phase, inhibiting the tubulin polymerisation, decreasing the level of ERK1/2, p-ERK and c-Jun proteins which effect the ERK signalling pathway in MCF-7 cancer cell lines.

Fig. 3 Hybrids of combretastatin-amidobenzothiazole.

Fig. 4 Dibenzo[*b,d*]furan-imidazole hybrids.

resulted in alteration of its cytotoxic activity (Fig. 4). Considering the anticancer activities of natural and synthetic 2-benzoylbenzofuran derivatives and the potent cytotoxic activities of imidazole derivatives, Wang *et al.*¹⁵ synthesized novel hybrids of 2-benzoylbenzofuran and imidazole analogs and evaluated their anticancer activity *in vitro*. Compound 5 and 6 showed the most significant activity against five strains of human cell lines, in particular, against the breast carcinoma (MCF) and myeloid liver carcinoma (SMMC-7721) cell lines. SAR showed that in compounds 5 and 6, substitution of imidazole ring at the third position by 4-methoxyphenacyl resulted in significant biological activity (Fig. 5). Benzimidazoles are known to have diverse biological activities and are of great significance. Various benzimidazole-linked triazolo-thiadiazole and triazolo-thiadiazines derivatives were synthesized and evaluated against the NCI 60 cell lines panel at the National Cancer Institute, USA. Among the synthesized compounds, 7 showed remarkable cytotoxicity against the MG-MID tumor cell lines.

Fig. 6 Benzimidazole linked with triazolo-thiadiazoles and triazolo-thiadiazines.

Furthermore, SAR studies have revealed that the presence of chloro group (electron withdrawing) on the *para*-position and *meta*-position of a phenyl ring played a significant role in enhancing the biological profile of the compound. The structure of the compound has been presented in Fig. 6.¹⁶

Active Hybrids	Imidazole ring	R ¹	X
5			Br
6			Br

Fig. 5 Imidazole scaffold-based 2-benzoylbenzofuran hybrids.

Fig. 7 Benzimidazoles with oxadiazole nucleus hybrids.

Considering the diverse biological activities of 1,3,4-oxadiazole derivatives, Rashid *et al.* designed novel oxadiazole nucleus-linked benzimidazole hybrids using a microwave irradiation method. Compound **8** (Fig. 7) was the most active compound with high growth inhibition against the full NCI cell lines panel. According to the SAR studies, the presence of NH_2 , 2-chloro, and 2,4-dichloro (electron-donating groups) on the phenyl ring at the 5 position of oxadiazole was responsible for the anticancer activity.¹⁷ Another study was based on the observations that isatin (1*H*-indole-2,3-dione) had interesting pharmacological profiles and toleration in human subjects. Solomon *et al.* fused isatin with benzothiazole and evaluated its

activity in breast cancer cell lines. Compound **9** (Fig. 8) showed a better effect with an improved safety profile. These effects were attributed to the arrest in the cell cycle at the G2/M phase.¹⁸

Dithiocarbamates are considered as a privileged scaffold for drug discovery with a wide range of biological activities. Duan *et al.*¹⁹ designed novel hybrids of 1,2,3-triazole dithiocarbamate-urea and evaluated them against human cancer cell lines. The IC_{50} value for hybrids **10** and **11** (Fig. 9) ranged from 1.62 to 20.84 and 0.76 to 13.55 μM , respectively. Another study was focused on developing the three series of novel imidazo [1,2-*b*] pyrazole type derivatives: C-2/C-3/C-6 tri (hetero) arylated, C-2/C-3/C-6/C-7 trisubstituted, and C-2/C-6/

Key findings

9 showed 10-15 fold higher cytotoxicity against cancer cells, low side effects and effective anticancer activity on breast cancer cells by arresting cell cycle at G2/M phase.

Fig. 8 Isatin–benzothiazole hybrids.

Fig. 9 1,2,3-Triazole-dithiocarbamate-urea hybrids.

C-7 trisubstituted imidazo [1,2-*b*] pyrazoles. Among the total synthesized compounds, **12**, **13**, and **14** displayed IC₅₀ values less than 10 μM in a 6-cell line panel. The SAR analysis revealed that C-7 amino-methylated compounds such as morpholine or *N*-methylpiperazine as a 6-membered cycle, are promising candidates for cancer treatment. The presence of a fourth substituent in the C-2/C-3/C-6/C-7 tetra-substituted imidazo [1,2-*b*] pyrazoles did not produce any significant

impact, except for compound **14**.²⁰ The chemical structure has been presented in Fig. 10. One more study suggested the impact of the nature of substitution on pyrimidine-benzimidazole hybrid molecules. The hybrid molecules were synthesized and evaluated for anticancer activity against 4 human cancer cell lines. Compounds **15** and **16** (Fig. 11) showed potent anticancer activity against MCF-7, MGC-803, EC-9706, and SMMC-7721 cell lines with the IC₅₀ values ranging from 2.03 to 10.55 μM and 1.06 to 12.89 μM, respectively. The results showed that compound **16** inhibited the proliferation of MGC-803 cancer cells by causing cell death and arresting the cell cycle at the G2/M phase.²¹ Computational assistance with a novel strategy of preparing some *N*-[6-indazolyl] aryl-sulfonamides and *N*-[alkoxy-6-indazolyl] aryl-sulfonamides has been reported.²² The major steps involved the reduction of 2-alkyl-6-nitroindazoles with tin(II) chloride using various alcohols, following the coupling of the

Fig. 10 Imidazo [1,2-*b*] pyrazoles.

Fig. 11 Novel pyrimidine-benzimidazole hybrids.

Fig. 12 Substituted indazole derivatives.

Fig. 13 Isoxazoline-containing natural products.

corresponding amine with arylsulfonyl chlorides in pyridine. Compounds **17** and **18** showed significant anticancer activity against A2780 (ovarian carcinoma) and A549 (lung adenocarcinoma) human tumor cell lines, with the IC_{50} values ranging from 4.21 to 18.6 μM . Furthermore, the results of immunofluorescence microscopy demonstrated that both compounds disrupted the microtubule network similar to the anti-microtubule agent vincristine, verifying the arrest at the G2/M phase of the cell cycle. The molecular docking studies helped in the identification of the paclitaxel binding site as the binding pocket for compound **18**, whereas compound **17**

was predicted to bind at an unidentified binding site at the α/β subunits interface (Fig. 12). Kaur *et al.* developed a class of isoxazoline derivatives as anticancer agents.²³ Some important synthetic Δ^2 -isoxazoline scaffolds discussed were 3,5-diaryl-isoxazoline-linked 2,3-dihydroquinazoline hybrids **19**, arylisoxazoline-containing anthranilic diamides **20**, 3,5-diaryl-isoxazoline-linked pyrrolo[2,1-c][1,4] benzodiazepine (PBD) conjugates **21**, and dibenzo [b,f] azepine-tethered isoxazoline derivatives **22** (Fig. 13).

Moreover, two series of novel 1,2,4-triazolo [3,4-a] phthalazine derivatives were synthesized and evaluated for their

Fig. 14 Novel 1,2,4-triazolo [3,4-a] phthalazine derivatives.

Fig. 15 1,2-Furanonaphthoquinones and 1,2,3-1H-triazole hybrids.

Fig. 16 Novel N-benzenesulfonyl-1,2,3,4-tetrahydroisoquinoline-based triazoles.

anticancer activity in the following human cancer cell lines: MGC-803, EC-9706, HeLa, and MCF-7.²⁴ When compared to the standard drug fluorouracil, compound **23** exhibited significantly high anticancer activity, with the IC_{50} values ranging from 2.0 to 4.5 μM . It was revealed from the flow cytometry analysis that compound **23** induced early cell apoptosis and cell cycle arrest at the G2/M phase. The phenyl group at the C-3 position of the compound was most active and showed better cytotoxic activity (Fig. 14). In another study, the novel hybrid molecules of 1,2-furanonaphthoquinones and 1,2,3-1H-

triazoles were synthesized and evaluated for their anticancer activity against four different leukemia cells: MOLT-4, CEM, K562, and KG1. Compounds **24** and **25** showed higher cytotoxic potential against all the tested leukemia cell lines as compared to the classical anticancer compounds such as doxorubicin and cisplatin (Fig. 15).²⁵ Moreover, the modified Pictet-Spengler reaction and click chemistry were used to synthesize a novel series of N-benzenesulfonyl-1,2,3,4-tetrahydroisoquinolines.²⁶ Compounds **26** and **27** were found to be the most potent anti-cancer agents and selected for molecular docking against the

Fig. 17 Thiazolo[2,3-b]quinazoline and thiazolo[3,2-a]pyrimidine analogs.

plausible target site AKRIC3. Compound **26** was the most potent compound against the cancer cell lines HuCCA-1, whereas the *p*-tolyl analog **27** displayed the most potent inhibitory activity against HepG2 cells. The potent and selective action of these compounds was because of the direct junction of their substituents at the R¹ and R² positions. The potent activity of compound **27** against HepG2 cells is due to the presence of the hydrophobic group and it binds to the target site of action *via* the hydrophobic region (Fig. 16).

A novel series of hybrid compounds were synthesized using thiazolo[2,3-*b*]quinazoline and thiazolo[3,2-*a*]pyrimidine analogs.²⁷ Amongst the synthesized compounds, **28**, **29**, **30**, and **31** showed significant anticancer activity when tested against 60 cancer cell lines at the National Cancer Institute, with the GI₅₀ MG-MID values of 2.4, 1.5, 11.2, and 3.1 μM, respectively (Fig. 17). A different study involved the synthesis of a series of 1,4-benzoxazine-1,2,3-triazole hybrids through a click chemistry approach, and the novel molecules were tested for *in vitro* cytotoxicity against human HeLa, MIA-PACA, MDA-MB-231, and IMR32 cell lines. Compound **32** showed significant activity against MDA-MB-231 and IMR32 cell lines. It was the first study reported on the synthesis and *in vitro* antiproliferative evaluation of 1,2,3-triazole-1,4-benzoxazine hybrids (Fig. 18).²⁸

The novel hybrid molecules were synthesized *via* the multi-component reaction of *N*-(prop-2-ynyl)-quinoxalin-2-amine derivatives with 2-iodoanilines and tosyl azide. The solvent system used was 10 mol% copper iodide and triethylamine in DMSO. The products **33** were achieved in good yields within 30 minutes without the use of a ligand and lateral addition of catalyst (Fig. 19). The anticancer activity studies revealed that these compounds induced significant apoptosis in zebrafish embryos.²⁹ In another study, green chemistry was applied to link the three pharmacophoric groups (quinoline, triazole, and dihydroquinoline) to form a novel series of hybrid molecules. The process involved one-pot sequential azidation and copper-catalyzed azide-alkyne cycloaddition (CuAAC) in water under mild conditions. The substitution was performed at the 1 and 4 position of 1,2,3-triazoles having quinolinyl methylene at N-1 and 1,2-dihydroquinolinyl methylene at the C-4 position. The synthesized compounds **34** were evaluated for anticancer activity against various cell lines and found to possess significant activity against lung cancer cells (Fig. 20).³⁰ Kuntala *et al.* synthesized novel benzoxepine-1,2,3-triazole hybrids *via* the application of the CuAAC approach. This rapid click reaction was performed by treating 7,9-disubstituted(*Z*)-4-(azidomethyl)-

5-chloro-2,3-dihydrobenzo[*b*]oxepine with terminal alkynes at room temperature using DMF as the solvent. The synthesized compounds **35** were found to be cytotoxic against lung and colon cancer cell lines (Fig. 21).³¹

3. Camptothecin-based hybrids

Camptothecin (CPT), a quinoline alkaloid with potent anti-tumor activities, was isolated from the Chinese plant *Camptotheca acuminata* by Wall *et al.* in 1996.³² It inhibits the DNA enzyme topoisomerase I by blocking the rejoining step of the cleavage/relegation of Topo-I. Topo I is an enzyme essential for cellular processes, participating in replication, transcription, and DNA repair. The major limitations related to CPT are low water solubility, inactivation of carboxylate salt, and short pharmacokinetic half-time. Thus, to overcome these limitations, Huang *et al.*³³ synthesized E-ring-modified camptothecin. The substitution of methylene in the E-ring resulted in a seven-membered β-hydroxy lactone E-ring, which resulted in stereoselective inhibition of TOPO-I. Similarly, Cincinelli *et al.*³⁴ synthesized camptothecin-linked platinum hybrids and assessed them against human tumor cell lines. Among these hybrids, compound **36** showed remarkable activity against the H460 tumor xenograft. This hybrid overcame the drawbacks

Fig. 18 1,4-Benzoxazinone-[1,2,3]triazole hybrids.

Structure of CPT (1), and binding to topo 1 and DNA.

Fig. 22 Camptothecin-based hybrids.

such as off-target effects, poor pharmacokinetic profile of the platinum drug, and DNA cleavage reversibility of camptothecin (Fig. 22).

4. Chalcone-based hybrids

Chalcone is an aromatic ketone and an enone that forms the central core for a variety of important biological compounds, which are known as chalcones or chalconoids. Chalcones have shown significant anticancer properties with their mode of action being similar to that of combretastatin. Chalcones bind to tubulin and prevent it from polymerizing microtubules, which is an important target for several anticancer agents. Chalcones can easily be prepared from substituted benzaldehydes that make it a privileged scaffold.³⁵ The major

advancements in the field of hybrid compounds derived from chalcones have been summarized below.

Considering the importance of chalcones, Kamal *et al.*³⁶ employed a solid-phase synthetic protocol to prepare a new class of C8-linked pyrrolo[2,1-*c*][1,4] benzodiazepine–chalcone hybrids *via* utilizing an intramolecular aza-Wittig reductive cyclization approach. Among these hybrids, compound 37 showed promising anticancer activity. Solid-supported synthetic method and aldol condensation were also utilized during the synthesis of these conjugates (Fig. 23). Nagaraju *et al.* applied the Claisen-Schmidt condensation to synthesize a new class of hybrid chalcones.³⁷ The synthesized compounds were tested for their anticancer activity against PC-3 (prostate cancer), HT-29 (colon cancer), B-16 (mouse macrophages), and NCI-H460 (lung cancer) cell lines. Compounds 38, 39, and 40

Pyrrolobenzodiazepine-chalcone hybrid design

Fig. 23 C8-linked pyrrolo[2,1-*c*][1,4] benzodiazepine–chalcone hybrids.

Fig. 24 Novel chalcone hybrids.

Fig. 25 Novel coumarin-chalcone hybrids.

(IC_{50} = 8.4, 7.9, and 5.9 μ M) showed significant anticancer activity, especially towards the PC-3 cell line. Since selectivity of a drug is an important parameter in cancer chemotherapy, further structural optimization of these compounds was carried out to improve the selectivity and it led to the preparation of more potential anticancer drug candidates (Fig. 24). Sashidhara *et al.* synthesized hybrids of coumarin and chalcones and carried out *in vitro* cytotoxicity studies against normal fibroblasts (NIH3T3) and a panel of four human cancer cell lines. Compound **41** was found to be the most potent, which showed about 30-fold more selectivity towards cervical carcinoma (C33A) cells over normal fibroblast NIH3T3 cells (Fig. 25).³⁸

Podophyllotoxin is a naturally occurring antitumor lignan lactone isolated from the genus *Podophyllum*. It acts by inhibiting tubulin polymerization and is used for the treatment of various types of cancers. Considering the importance of podophyllotoxin, Kamal *et al.* synthesized podophyllotoxin tethered to 4- β -alkylamidochalcone and 4- β -cinnamido hybrids and

assessed them for their anticancer activity in 5 human cancer cell lines.³⁹ When compared to etoposide, hybrids **42** and **43** showed potent activity against the A-549 cancer cell line with the IC_{50} values of 2.7 and 2.1 μ M, respectively. It induced caspase-3-dependent apoptotic cell death by arresting the cell cycle at the G2/M phase. The results were evaluated through flow cytometric analysis (Fig. 26). As is well-known, chalcones possess anti-tumor properties, triazoles have various biological activities (including anticancer profile), and β -lactam compounds (ever-green bioactive molecules) can widely and safely be used without significant toxicity. This information motivated Singh *et al.*⁴ to fuse these three moieties using azide-alkyne cycloaddition reactions and click chemistry approach. It resulted in the synthesis of novel 1,2,3-triazole-tethered β -lactam chalcone bifunctional hybrids, which were assessed against four human cancer cell lines. SAR studies showed that methoxy substitution at the *ortho*-position in ring A and *para*-position in ring B on chalcone enhanced the anticancer activity of these hybrids. Among the hybrids, compound **44** showed remarkable activity against A-549 (lung), PC-3 (prostate), THP-1 (leukemia), and Caco-2 (colon) cell lines with the IC_{50} value < 1, 67.1, <1, and 6.37 μ M, respectively. In another study, nitrogen oxide (NO), which is an important mediator in biological systems, was found to prevent tumor cells from metastasizing and facilitated macrophages to kill the tumor cells. The nitric oxide-donating moieties such as nitrate ester, oximes, and furoxans were linked to amino chalcones to synthesize NO-donating chalcone hybrids as anticancer agents.⁴⁰ Among the hybrids, compound **45** and **46** showed significant activity against colon and melanoma cancer cell lines and also showed anti-inflammatory activity with less ulcerogenic liability. The significant anti-cancer potential of chalcones and PBD encouraged Kamal *et al.*⁴¹ to design anticancer hybrids using the click chemistry approach. A novel series of A-C8/C-C-2 chalcone-linked pyrrolo [2,1-*c*][1,4] benzodiazepine hybrids were synthesized and connected by 1,2,3-triazole side-armed alkane spacers. These hybrids were then extensively evaluated towards the MCF-7 cancer cell lines. The results of the MTT proliferation assay revealed hybrid **47** as the most potent anti-proliferative agent. It showed its action through a GI cell cycle arrest with an effect on the protein cyclin D1 and Cdk4 (Fig. 27). Novel pyrano chalcone derivatives containing indole moiety were synthesized and evaluated for their anticancer activities. Compound **48** emerged

Fig. 26 4 β -Alkylamidochalcone and 4 β -cinnamido-linked podophyllotoxins hybrids.

Fig. 27 1,2,3-Triazole-tethered β -lactam-chalcone bifunctional hybrids.

as the most potent cytotoxic agent against all cancer cell lines, with the IC₅₀ values ranging from 0.22 to 1.80 μ M. This compound also induced cell cycle arrest at the G2/M phase and inhibited the polymerization of tubulin (Fig. 28).⁴²

A novel series of chalcone hybrid analogues containing an anthraquinone scaffold and an imine fragment was synthesized and evaluated for anticancer activity against HeLa, LS174, and A549 cancer cells.³⁸ The most potent compound **49** had an imino group linked to a furan ring. It was revealed from the mode of action studies that this compound induced the changes that were essential for apoptosis in HeLa cells (Fig. 29).

Fig. 29 Anthraquinone-based chalcone analogue.

Furthermore, a novel series of anthraquinone-based chalcone compounds was synthesized by the Claisen-Schmidt reaction using 1-acetylanthraquinone as the starting material. Compounds **50**, **51**, and **52** showed low cytotoxicity against

Fig. 28 Pyrano chalcone derivatives.

Fig. 30 Anthraquinone-chalcone hybrids.

Fig. 31 Novel chalcone triazoles.

healthy MRC-5 cell lines and inhibited HeLa cells with the IC_{50} values ranging from 2.36 to 2.73 μM . The flow cytometry studies confirmed that these compounds caused cell arrest at the S and G2/M phases and induced caspase-dependent apoptosis. These compounds also exhibited calf thymus DNA-binding activity (Fig. 30).³⁹ Chinthala *et al.* synthesized a novel series of chalcone-triazole derivatives that were evaluated for *in vitro* anticancer activity against IMR32 (neuroblastoma), HepG2 (human hepatoma), MCF-7 (human breast adenocarcinoma), DU-145 (human prostate carcinoma), and A549 (human lung adenocarcinoma) cell lines. Compound 53 was found to be most potent as it showed significant anticancer activity against all the cell lines (Fig. 31).⁴³

5. Pyrrolo [2,1-c][1,4] benzodiazepine (PBD)-based hybrids

Pyrrolo [2,1-c][1,4] benzodiazepines (PBDs) are naturally occurring DNA interactive antitumor antibiotics isolated from various *Streptomyces* species. DC-81 and anthramycin are some of the typical examples of PBDs.⁴⁴ The PBD cytotoxins exert powerful antitumor activity by covalently binding at the C-11 position of PBD and the C-2 amino group of the guanine residues within the minor groove of double-stranded DNA. Hybrids with antitumor agents linked to PBD have been discussed below.

Considering the structural modification of PBD and the important anticancer activities of benzothiazoles as well as isosteric benzoxazoles, Kamal *et al.*⁴⁵ synthesized a series of benzothiazole/benzoxazole-PBD hybrids. Alkane and alkylamide spacers attached to the conjugates of benzothiazole and benzoxazole-linked pyrrolobenzodiazepine were prepared and evaluated for their anticancer activity. The synthesized compounds were also investigated for DNA thermal denaturation studies and restriction endonuclease digestion. Among

Fig. 32 Benzothiazole/benzoxazole-pyrrolo[2,1-c][1,4] benzodiazepine (PBD) hybrids.

the hybrids, compound 54 showed potent anticancer activity *via* arresting or stopping the apoptosis. SAR studies showed that the presence of a sulphur atom in benzothiazole and the 5-carbon chain length resulted in high DNA-binding ability of minor groove binders with the SEQ-A and A375 cell line at a low concentration of 0.5 μM (Fig. 32).

Moreover, estrogen receptor, a key biological target over the years, has attracted significant interest since it is expressed in many cancers. Therefore, estradiol and its related receptor can be used to direct a cytotoxic agent to the target cells. This information was utilized by Kamal *et al.* for the synthesis of estradiol-linked pyrrolobenzodiazepine (PBD) conjugates as anticancer agents.⁴⁶ Among the 18 synthesized conjugates, compound 55 was most potent against the breast cancer cell line MCF-7. Active conjugate 55 was synthesized by the reduction of nitro groups using hydrated stannous chloride in the presence of methanol. Cyclization and deprotection were carried out using mercuric chloride and calcium carbonate. Fragmentation of nuclei followed by disruption of microtubules resulted in a CDK1 inhibitor property of the active compound (Fig. 33). Naphthalimides with charge transfer and stacking between base pairs act as DNA-intercalating agents with high antitumor activity. Using this information, Kamal *et al.* synthesized novel pyrrolobenzodiazepine-naphthalimide conjugates 56, 57, and 58 with high DNA binding affinity. These unique bi-functional compounds showed *in vitro* activity against some cancer cell lines (Fig. 34).⁴⁷ In another study, the novel hybrids of pyrene-linked pyrrolo[2,1-c][1,4]

Fig. 33 Estradiol-linked hybrid molecules.

Fig. 34 PBD–naphthalimide hybrid molecules.

Fig. 35 Pyrene-linked hybrid molecule.

benzodiazepines were synthesized⁴⁸ and found to exhibit effective anticancer activity against various human tumor cell lines. Among all the synthesized conjugates, hybrid **59** showed maximum anticancer activity against 60 cancer cell lines (Fig. 35).

Benzothiadiazine–pyrrolobenzodiazepine-linked hybrids were synthesized and evaluated for cytotoxicity against many cancer cell lines. Among the synthesized PBD hybrids,⁴⁹ compound **60** was found to be most effective as it increased the temperature of CT DNA by 6.7 °C after incubation for 36 hours. SAR studies showed that 1,2,4-benzothiadiazine was linked to the C-8 position of the PBD ring through a piperazinyl alkane

Fig. 36 1,2,4-Benzothiadiazine-linked pyrrolo[2,1-c][1,4]benzodiazepine hybrids.

Fig. 37 3,5-Diaryl-isoxazoline/isoxazole–pyrrolobenzodiazepine conjugates.

spacer and analyzed as a new possible anticancer agent. This hybrid showed significant *in vitro* anticancer activity against breast, oral, and prostate human cancer cell lines along with impressive DNA-binding strength (Fig. 36). Another study involved the synthesis of a series of 3,5-diaryl-isoxazoline/isoxazole-linked pyrrolo [2,1-c][1,4]benzodiazepine (PBD) conjugates, which were evaluated for anticancer activity.⁵⁰ Further investigations on these conjugates were performed for cell cycle disruption, which led to subsequent apoptotic cell death. The PBD conjugate **61** was selected for the preclinical studies since it was the most potent among all the synthesized compounds. The GI₅₀ value for this compound was in the range of 0.1–2.15 μM. The improved anticancer activity was due to the linking of 3,5-diaryl-isoxazoline/isoxazole moiety to the PBD ring system (Fig. 37). Wang *et al.* synthesized novel hybrids of [2,1-c][1,4]benzodiazepine (PBD) and indole carboxylates.⁵¹ The carbon chain linkers were used to link the C-8 position of DC-81 with the indole 2-carbonyl moiety to form the high yield compounds **62** and **63**. The preliminary tests confirmed that these compounds possessed potent anticancer activity. These compounds showed higher cytotoxicity and better DNA binding ability towards human melanoma A2058 cells. The NCI screening results suggested that these compounds can be used as potent broad spectrum anticancer agents that inhibit the growth of a variety of cancer cell lines (Fig. 38).

The novel conjugates of a series of benzo[*c,d*]indol and 2(1*H*) one-PBD were designed and synthesized as potential anticancer agents. The C-8 position of DC-81 was linked with a benzo[*c,d*] indol-2(1*H*)one moiety through different alkane spacers. The MTT assay method was used to evaluate these compounds for their anticancer activity in selected human cancer cell lines of lung, skin, colon, and prostate. Among these compounds, **64** was the most potent and showed promising anticancer activity as confirmed by Annexin V-FITC, Hoechst staining, caspase-3 activity, and DNA fragmentation analysis. It was confirmed *via*

Fig. 38 Pyrrolo[2,1-c][1,4]benzodiazepine and indole hybrids.

Fig. 39 Benzo[c,d]indolone-pyrrolo[2,1-c][1,4]benzodiazepine hybrids.

FACS analysis that compound **64** had cell cycle regulatory properties since cell death occurred due to cell cycle arrest at the SubG1 phase. The most important property of this compound was that it did not affect the normal cell line (HEK-293) (Fig. 39).⁵²

Acridine and acridone-based compounds consist of an important class of DNA-intercalating anticancer drugs. The anticancer hybrid compounds were prepared by linking the pyrrolo[2,1-c][1,4]benzodiazepine hybrids with the acridone/acridine ring systems at the C8-position.⁵³ Compound **65** was found to be the most potent among the synthesized compounds (Fig. 40). Moreover, another study was based on the synthesis of a novel

series of bisindole-pyrrolo[2,1-c][1,4]benzodiazepine conjugates, which were linked through different alkane spacers.⁵⁴ The most potent compounds were **66** and **67**, which showed significant anti-cancer activity and subjected to a detailed study towards the MCF-7 cell line. It was found *via* the flow cytometric (FACS) analysis that there was an increase in the sub-G1 phase cells and a decrease in the G2/M phase cells, which caused apoptosis in the MCF-7 cells. The apoptotic cell death was due to the down regulation of the levels of histone deacetylase protein, such as HDAC-1,2,3,8, and an increase in the levels of p21. The increased expression of cleaved-PARP and active caspase-7 in MCF-7 cells further confirmed the apoptotic nature of cell death (Fig. 41).

Novel hybrids of quinazoline linked to pyrrolo[2,1-c][1,4]benzodiazepines were synthesized. Thermal denaturation studies showed that compounds **68** and **69** possessed better DNA binding ability as compared to DC-81. These compounds also exhibited crucial cytotoxicity towards A375 cells at 4 μM . The results were validated through an MTT assay (Fig. 42).⁵⁵ In another study, a novel series of anthranilamide-fused pyrrolo [2,1-c] [1,4] benzodiazepine hybrids was synthesized and evaluated against the A374 cancer cell line. PBD hybrid **70** showed remarkable activity by inducing apoptosis through caspase-3 activation and increasing the level of p-53 (master regulator of apoptosis). SAR studies showed that in the active hybrid compound, the anthranilamide moiety was fused at the C-8 position of the A ring in the PBD ring system through a 4-piperazinyl alkane spacer, which resulted in effective anti-cancer activity (Fig. 43).⁵⁶

6. Coumarin-based hybrids

Coumarin, belonging to the benzopyrone chemical class, is a fragrant organic chemical compound. It is a colorless, crystalline substance in its standard state. Coumarin exhibits antitumour activity *in vivo*, with the effect believed to be due to its metabolites such as 7-hydroxycoumarin.⁵⁷ Some coumarin-based hybrids have been discussed below.

The naturally occurring coumarins and resveratrol possess significant anticancer activity. Belluti *et al.* synthesised and evaluated a new class of hybrid compounds by attaching a substituted *trans*-vinylbenzene moiety on a coumarin backbone that exhibited high antitumor activity.⁵⁸ Compounds 71 and 72 were highly active compounds among this series, having

excellent antiproliferative and proapoptotic activities. The excellent antitumor activity was due to the presence of the 7-methoxycoumarin nucleus, together with the 3,5-disubstitution in the *trans*-vinyl benzene moiety. Compounds 71 and 72 were tested against H460 lung carcinoma cells and they exhibited pharmacologically relevant antiproliferative activity. Comprehensive biological investigations revealed that these compounds had the ability to induce an appreciable level of apoptosis (Fig. 44). Amin *et al.*⁵⁹ synthesized a novel series of coumarin-pyrazole hybrids by cyclizing coumarin chalcones with various substituted hydrazines through 1,4-addition on an α,β -unsaturated carbonyl system to produce the corresponding pyrazolines. The synthesized compounds were investigated against 60 cancer cell lines for their anticancer activity. Most of the compounds were effective against the breast cancer cells MCF7 and colon cancer cells HCT-116. Among these, compound 73 possessed the highest cytotoxicity, but it showed weak enzyme inhibitory activity against P13K (Fig. 45). Chen *et al.* designed and synthesized novel triphenylethylene-coumarin hybrid derivatives, having different amounts of amino side chains, under microwave radiations.⁶⁰ The compounds with two amino side chains (except for morpholino) exhibited broad-spectrum and good antiproliferative

Fig. 44 Coumarin-stilbene hybrid molecules.

Fig. 45 Coumarin–pyrazoline hybrid design.

Fig. 46 Coumarin–triphenylethylene hybrid molecule.

Fig. 47 Coumarin–benzimidazole hybrid molecule.

activity against five tumor cell lines. These compounds also possessed low cytotoxicity in osteoblast. SAR analysis revealed that the amino alkyl chain had an important role against tumor cell proliferation as well as DNA interactions. Compound 74 showed good anticancer activity and significant binding with

DNA. The study suggested that DNA might be one of the potential targets for triphenylethylene–coumarin hybrids as anticancer agents (Fig. 46).

Novel hybrids of coumarin and benzimidazole were synthesized and evaluated as antitumor agents.⁶¹ Among the hybrids, compound 75 showed remarkable suppression for cancer cell lines of leukemia, colon, and breast cancer. The SAR studies revealed that the substitution at the 7-position of coumarin–benzimidazole hybrid and the H-bond interaction with TOPO 2, RNA, and DHFR resulted in its great activity and selectivity against cancer cell lines (Fig. 47). Derivatives of coumarin–monastrol (compound 76) were synthesized and assessed as anti-breast tumor specific agents.⁶² The increase in the number of methoxy groups on the benzene ring that substituted the coumarin ring resulted in a significant increase in the anti-cancer activity against breast cancer (Fig. 48). A series of selective Hsp90 inhibitors 77 was developed by the structural modification of novobiocin, which is an antibiotic that acts through inhibition of DNA gyrase.⁶³ The SAR studies revealed that the anticancer activity was known to be in the nM range and was due to the replacement of novose sugar and phenyl ring of the benzamido moiety with appropriate groups. The excellent anticancer activity was achieved *via* certain sugar replacements, such as pyranose, a sugar mimic, and piperidine, an aza sugar mimic. The coupling of arylsulfonamides with multifaceted coumarin led to the formation of a series of coumarin-3-sulfonamides that possessed potent anticancer activity against different cell lines. Compound 78 was synthesized by exploring various substituents at different positions of the phenyl and coumarin nuclei (Fig. 49).

The novel chalcone–coumarin hybrids were prepared through azide/alkyne dipolar cycloaddition reaction by the linkage of 1,2,3-triazole ring.⁶⁴ When compared to the standard drug etoposide, compounds 79 and 80 exhibited higher inhibitory efficacy in HepG2 cells. The compound 79 was found to be non-toxic to normal cells (Fig. 50). Yadagiri *et al.*⁶⁵ synthesized

Fig. 48 Coumarin–monastrol hybrid molecule.

Fig. 49 Novel novobiocin analogs.

a novel series of benzosuberone-bearing coumarin moieties. The synthesized structures were determined *via* analytical and spectral studies. Among the synthesized compounds, **81** exhibited significant anticancer activity against all the cancer cell lines such as A549, HeLa, MCF-7, and MDA-MB-231, whereas compound **82** was cytotoxic against HeLa and MDA-MB-231 cell lines (Fig. 51). A novel group of compounds was

Fig. 50 Novel chalcone-coumarin hybrids.

Fig. 51 Synthesis of novel benzosuberone-bearing coumarin moieties.

synthesized containing fused tricyclic coumarin sulfonate as the key molecule.⁶⁶ On testing the compounds against 57 human cancer cell lines, **83**, **84**, and **87** were found to be more selective against leukemia and colon cancer subpanels, whereas compounds **85** and **86** showed broad-spectrum anticancer activities (Fig. 52).

A series of novel coumarin-substituted hydrazide-hydrazone derivatives **88** was synthesized and evaluated for its anticancer activity against Panc-1, Hep-G2, and CCRF cell lines.⁶⁷ The results revealed that 6-brominated coumarin hydrazide-hydrazone derivatives showed higher cytotoxicity than doxorubicin against resistant Panc-1 cells. Among these compounds, a few showed significant anticancer activity against all the tested cells, whereas others were only cytotoxic against the resistant Panc-1 cells (Fig. 53). Zhang *et al.*⁶⁸ synthesized a series of 4-(1,2,3-triazol-1-yl) coumarin derivatives and evaluated it for anticancer activity against three human cancer cell lines: human breast carcinoma MCF-7 cell, colon carcinoma SW480 cell, and lung carcinoma A549 cell. The biological potency was increased by conducting structural optimization at the C-4 position of 1,2,3-triazole and the C-6 and C-7 positions of coumarin. Compound **89** exhibited excellent anticancer activity by arresting the G₂/M cell cycle and inducing apoptosis (Fig. 54). A new method was developed for the synthesis of coumarin-containing α -aminophosphonates having two chiral centers.⁶⁹ The single-crystal structure compounds were evaluated for their anticancer activity against human pulmonary carcinoma cell line (A549), human nasopharyngeal carcinoma (human KB), and human lung adenocarcinoma (MGC-803) cell lines. Compound **90** exhibited the best anticancer activity due to the influence of chirality in the DNA-binding assay since this compound exhibited a higher binding constant (Fig. 55).

Fig. 53 Coumarin-substituted hydrazide-hydrazone derivatives.

Fig. 54 4-(1,2,3-Triazol-1-yl) coumarin derivatives.

Fig. 55 Coumarin containing aminophosphonates.

4-*H*-Benzo[*h*]chromene and 7*H*-benzo[*h*]chromeno[2,3-*d*]pyrimidine derivatives were synthesized and evaluated for anticancer activity *via* comparison with the standard drugs vinblastine, colchicine, and doxorubicin using MTT calorimetric assay.⁷⁰ Compounds 91, 92, 93, and 94 were most potent against the three tumor cell lines MCF-7, HCT, and HepG-2. The SAR studies of 4*H*-benzo[*h*]chromenes with modifications at the 2- and 3-positions and 7*H*-benzo[*h*]chromeno[2,3-*d*]pyrimidine

Fig. 56 Highly active chromene derivatives.

Fig. 57 4-(3-Hydroxy-benzofuran-2-yl) coumarins.

Fig. 58 Novel coumarin–chalcone hybrid.

at the 2 and 3-positions revealed that the anticancer activity was significantly affected by the lipophilicity of the substituents at the 2- and 3- and 2 and 3-positions, respectively (Fig. 56). Various substituted benzoic acid methyl esters were prepared by reacting 4-bromo-methylcoumarins with methyl salicylate.⁷¹ The cytotoxicity studies revealed that compound **95** was more potent than the standard 5-fluorouracil (Fig. 57). Another study reported the mechanism of action and *in vivo* efficacy of the potent compound **96**.⁷² Upon oral administration of this compound, a significant decrease in tumor level induced by HeLa cell xenografts was observed in nod SCID mice. This compound also inhibited the growth of cervical cancer cells (HeLa and C33A) by arresting the cell cycle at the G2/M phase and inducing apoptosis (Fig. 58). A novel series of coumarin–

pyrazoline hybrids was synthesized along with a series of coumarins bearing non-cyclic isosteres of pyrazolines.⁷³ The synthesized compounds were evaluated for cytotoxicity against the HepG2 cell line. The most active compounds **97** and **98** were examined for telomerase inhibition and apoptosis induction. The results revealed that the compounds inhibited telomerase up to 78.6% and induced apoptosis in a dose-dependent manner (Fig. 59).

7. Colchicine-based hybrids

Colchicine is a classical tubulin-binding agent, which is isolated from *Colchicum autumnale* (meadow saffron). It binds to a second lower affinity site on tubulin and changes its secondary structure, which further hinders the formation of microtubules.⁷⁴ Some chemical modifications in colchicine and its derivatives have been discussed below.

The synthesis and design of a new class of colchicine–SAHA hybrids were carried out by Zhang *et al.*⁷⁵ These were the first designed molecules that were dual inhibitors of tubulin and HDAC. Compound **99** exhibited the strongest HDAC inhibitory activity and powerful antiproliferative activity against five cancer cell lines. The inhibitory activity of this compound was evaluated under both cell-free conditions and in *in vitro* cell cultures. The tubulin inhibition activity was not hampered by the linkage of SAHA to colchicines (Fig. 60). Malysheva *et al.*⁷⁶

Fig. 62 Novel allocolchicine analogue.

Fig. 63 Novel colchicine derivative.

synthesized novel bivalent hybrids of colchicine and tubulizine using a 1,3 dipolar cycloaddition reaction. These hybrids were then assessed against HBL100 epithelial cells. The active compound **100** exhibited the IC_{50} value ranging from 0.599 to 2.93 μM , possessing effective cytotoxicity. SAR studies showed that this hybrid was prepared *via* copper-mediated 1,3-dipolar cycloaddition reaction, and a flexible spacer was used to connect the azide-containing diacetyl colchicine and acetylene-substituted tubulizine entities. The colchicine moiety was

linked to 239Cy β and the tubulizine moiety was linked to 12Cy β of the protein molecule (Fig. 61). In another study, a novel derivative of allocolchicine **101** was synthesized and tested for anticancer properties.⁷⁷ The results suggested that compound **101** induced pro-death autophagy in pancreatic cancer cells and E6-1 leukemia cells without affecting normal human cells. It did not affect tubulin polymerization and increased the production of reactive oxygen species (ROS) in mitochondria that were isolated from pancreatic cancer cells. This compound is one of the best examples to demonstrate how a small change in the structure of colchicines apparently changes the mechanism of action and leads to improved selectivity (Fig. 62).

Moreover, a new series of colchicine derivatives was synthesized and evaluated for its anticancer activity.⁷⁸ Compound **102** exhibited potent anticancer activity by modulating the microtubule integrity and arresting the cell cycle at the G2/M phase before apoptosis. It was observed from the optical density analysis study using purified tubulin that this compound had a higher repolymerizing activity than taxol. The results suggested that this compound had different microtubule integrity compared to colchicine (Fig. 63). Researchers have been developing various innovative strategies for designing better and effective cancer drugs that can act upon two or more targets at the same time. One of these strategies involves the incorporation of the colchicine pharmacophore into combretastatin to form a hybrid compound combretatropone **103** (Fig. 64). This compound was evaluated for its cytotoxic activity *via* examining its drug interaction studies with tubulin. Promising results were achieved in the preliminary phase of the study, and further results are being awaited as the drug is still under clinical trials.⁷⁹

8. Platinum-based hybrids

Graham *et al.* synthesized a novel series of carboxylic ester group-attached platinum–acridine hybrids.⁸⁰ The synthesized compounds formed monofunctional-intercalative DNA molecules without cross-linking the DNA and were found to have significant antitumor activity. Among the conjugates, active hybrid **104** showed 6-fold higher activity against ovarian cancer (OVCAR-3) and breast cancer (MCF-7, MDA-MB-231) as compared to cisplatin (Fig. 65). Ding *et al.*⁸¹ synthesized a novel pharmacophore for the treatment of breast cancer using carbamate coupling chemistry by including a DNA-targeted platinum–acridine hybrid agent and estrogen receptor-

Fig. 64 Colchicine–combretastatin hybrid compound.

Fig. 65 Platinum-acridine hybrid.

targeted 4-hydroxy-*N*-desmethyltamoxifen (endoxifen). Upon evaluation in breast cancer cell lines, compound **105** was found to be most potent (Fig. 66). Moreover, the novel hybrids of 17β-estradiol platinum(II) **106** were synthesized from estrone through five-step chemical methods.⁸² SAR studies showed that the hybrid molecules were formed by linking different lengths of polyethylene glycol (PEG) chains and 2-(2-aminoethyl) pyridine ligand. MTT assay further revealed that hybrids with the longest PEG chain resulted in effective activity against MCF-7 and MDA-MB-231 breast cell cancer lines (Fig. 67). In another study, novel 17β-estradiol-linked platinum(II) hybrids **107** were synthesized and their biological activities were assessed against uterine and ovarian cancer cell lines.⁸³ These novel conjugates showed better activity towards the estrogen receptor α (ERα). The newly synthesized estrogen-Pt(II) hybrids had the IC₅₀ values ranging from 0.3 to 2.26 μM, which were far better than the natural ligand 17β-estradiol. The presence of the 16-β hydroxymethyl group provided more hydrogen bonds to the estrogen receptor, making the hybrids cytotoxic towards platinum-resistant endometrial and ovarian cell cancer cell lines (Fig. 68).

9. Miscellaneous hybrids

Kumar *et al.*⁸⁴ synthesised a series of tetrahydro-β-carbolines and 1,3,5-triazine hybrids that led to the discovery of new

Fig. 67 17β-Estradiol-platinum(II) hybrid.

Fig. 68 Estrogen-platinum(II) hybrids.

racemic compounds **108**, **109**, and **110**, which were selectively cytotoxic towards KB (oral cancer) cell lines. These compounds were evaluated for anticancer activity against a panel of eight human cancer cell lines and normal human fibroblasts (NIH3T3). Their IC₅₀ values were reported to be 105.8, 664.7, and 122.2 μM. Although these compounds were active towards KB cell lines, their enantiopure forms were less active and non-selective. The enantiopure compounds were 2.5 times more selective towards MCF7 cells than towards normal fibroblast NIH3T3 cells and induced apoptosis in MCF7 and MDA MB231 cell lines (Fig. 69). Cancer is caused by the hyperactivation of the PI3K/AKT/mTOR signaling pathways. Promotion of tumor growth is due to the synergistic effect of P13K and mTOR. Thus, strong and synergistic anticancer activity can be achieved *via* combined targeting of PI3K and mTOR. The novel wortmannin-rapamycin conjugates linked with a prodrug linker were synthesized using this approach.⁸⁵ This led to the synthesis of compound **111**, which completely inhibited the growth of HT29 tumors at a dose of 15 mg kg⁻¹. When administered alone or in

Fig. 66 Platinum-acridine-endoxifen hybrid.

Fig. 69 (Tetrahydro-β-carboline)-1,3,5-triazine hybrids design.

Fig. 70 Wortmannin-rapamycin hybrid.

Fig. 71 Dictyostatin-discodermolide hybrid.

combination with bevacizumab, this compound exhibited superior efficacy in the A498 renal tumor model (Fig. 70). Discodermolide and dictyostatin exhibit significant anticancer activity against cancer cells, and the mode of action is *via* accumulation of cells at the G2/M phase and cell death by apoptosis. Encouraged by this, Paterson *et al.*⁸⁶ designed and synthesized the novel hybrids of dictyostatin and discodermolide **112**, which showed improved cell growth

inhibition in four human cancer cell lines including taxol-resistant NCI/ADR-Res cell line (Fig. 71).

One of the methods to treat cancer is hybridization of two different bioactive molecules with different mechanisms of action. This approach led to the synthesis of novel anticancer agents by linking two series of N-3-substituted-5-arylidene thiazolidine-2,4-diones with α-bromoacryloylamido moiety at the *para*- or *meta*-position in the phenyl ring of the arylidene portion.⁸⁷ Compounds **113**, **114**, and **115** were found to induce apoptotic cell death by activating multiple caspases and releasing cytochrome-c from mitochondria. These compounds contain a pair of Michael acceptors in their structures. When evaluated against HL-60 and U937 cells, these compounds showed certain apoptotic features such as cell shrinkage, chromatin condensation, and fragmented nuclei by activating the extrinsic and intrinsic pathways of cell death (Fig. 72). Gupta *et al.*⁸⁸ synthesized a series of estradiol-chlorambucil hybrids and evaluated it for site-directed chemotherapy of breast

Fig. 72 Thiazolidine-benzylidene hybrid design.

cancer. Different hormone-dependent and hormone-independent breast cancer cell lines were used for the evaluation of anticancer efficacy of these newly synthesized compounds. When compared to chlorambucil, the novel hybrids showed significant *in vitro* anticancer activity. The length of the spacer chain between the carrier and drug molecule was revealed *via* structure–activity relationship (SAR) studies. Compound **116** showed significant cytotoxic activity against hormone-dependent (MCF-7) and hormone-independent (MDA-MB-436 and MDA-MB-486) breast cancer cell lines (Fig. 73). The novel indenoindolones were prepared as potential anticancer agents *via* scaffold hybridization of various natural and synthetic anticancer leads.⁸⁹ When compared to etoposide and 5-fluorouracil, these compounds showed highly potent anticancer activity in kidney cancer cells (HEK 293) and low toxicity in corresponding normal cells. The apoptotic effect was attributed to the cell cycle arrest at the G2/M phase. Compounds **117** and **118** were found to exhibit higher cytotoxicity among all the synthesized indenoindolones. These compounds caused 50% cell death (LC_{50}) of HEK 293 cells. On treatment of the cells with these compounds, increase in the punctate, bubble shape, and shrinkage nuclei of HEK 293 cells were observed. The exact biological target for anticancer activity of these indenoindolones is not yet known; however, the possible target may be proteins, such as cyclins and cyclin-dependent kinase (CDKs) families, p21 and p53, that are responsible for the G2/M phase of the cell cycle. Western blot analysis further revealed the increased levels of BAX/BCL-XL ratio and cleaved product of caspase-3 and PARP, indicating apoptotic effects of these compounds (Fig. 74).

Indole and barbituric acids are well known for their different biological activities such as anticonvulsant, anti-hypnotic, anti-cancer, and anti-inflammatory. This information motivated Singh *et al.*⁹⁰ to design and synthesize new hybrid molecules by combining the structural features of indole and barbituric acid. Compound **119** showed significant anticancer activity when evaluated over a 60 cell line panel of human cancer cells of non-small cell lung cancer (NSCLC), colon cancer, CNS cancer, ovarian cancer, renal cancer, and breast cancer (Fig. 75). Protoporphyrin is an efficient first-generation photosensitizer

Fig. 74 Scaffold hybridization of indenoindolones.

Fig. 75 Hybrids of indole and barbituric acids.

approved for photodynamic therapy (PDT) and treatment of neoplastic diseases. Sol *et al.* synthesized conjugates of tritoly-porphyrin and protoporphyrin-IX, **120** and **121**, by the five-step method.⁹¹ Photocytotoxicity of protoporphyrin conjugate was tested against K562 human chronic myelogenous leukemia cells, and the conjugate exhibited better activity. Structure–activity relationship studies showed that these conjugates were composed of polyamine units of either spermidine or spermine, which were also attached to two molecules of polyamine-bearing protoporphyrin-IX. Presence of spermidine and spermine in the active conjugate protoporphyrin-IX increased the amphiphilic character and phototoxicity of the conjugate. Protoporphyrin-IX polyamine derivative with log *P* value near 0 was soluble in water (Fig. 76). R-roscovitine, a 2,3,9-trisubstituted purine, is an inhibitor of cyclin-dependent kinase (CDK).

Fig. 73 Estradiol–chlorambucil hybrid.

Fig. 76 Polyamine conjugates design.

Fig. 77 Roscovitine-NO hybrid molecule.

Fig. 78 Isosteviol-linked pyrazoline and pyrazole hybrids.

CDKs regulate many biological functions such as cell division, transcription, neural cell physiology, and apoptosis, whereas nitric oxide (NO) also plays an important role in apoptosis, exerts pro-apoptotic or anti-apoptotic effects depending on the NO-donors. On this basis, Montanaro *et al.*⁹² designed and synthesized novel hybrids by linking R-roscovitine to different NO-donor molecules. These hybrids were assessed as pro-resolution agents. Among these hybrids, compounds 122 and 123 showed remarkable pro-apoptotic activity (Fig. 77). Zhu

et al. synthesized novel isosteviol-fused pyrazoline and pyrazole hybrids *via* intramolecular 1,3-dipolar cycloaddition and condensation reactions.⁹³ Novel hybrids were then assessed for their anticancer activity against malignant cancer cell lines such as SGC, 7901, A549, Raji, and HeLa. The hybrid compound 124 showed remarkable inhibition against malignant cancer cell lines with the IC_{50} values of 2.17, 3.18, 10.9, and 13.52 μM , respectively (Fig. 78). Sharma *et al.*⁹⁴ synthesized benzimidazole-quinazoline hybrids and assessed them *in vitro* against 60 tumor cell lines. Among the hybrids, compound 125 showed remarkable activity against cancer cell lines. SAR studies showed that the substitution of alkyl or allyl groups on benzimidazole and aryl groups of quinazoline ring increased the lipid solubility of the hybrid compounds. The substitution of pyrrolidine moiety and other secondary amines at the 2-position of quinazoline also increased the activity of the compound (Fig. 79).

Acetogenins are polyketides having one to three tetrahydrofuran (THF) rings and are connected to the α,β -unsaturated- γ -lactone ring *via* a long hydrocarbon chain. They exhibit a broad range of biological activities including cytotoxic, immunosuppressive, and antitumor activities. They act by inhibiting mitochondrial NADH ubiquinone oxidoreductase, which leads to the suppression of ATP production and results in apoptosis of cancer cells. Encouraged by this information, α - β unsaturated γ -lactone-free nitrogen-containing hybrids 126 were synthesized by Kojima *et al.* and evaluated for cytotoxicity against 39 tumor cell lines. Among these, the 1-methyl-pyrazol-5-yl derivative showed potential activity towards the NCI-H23 cancer cell line (Fig. 80).⁹⁵ A novel series of pyrazolo [1,5- α] pyrimidine-linked aminobenzothiazole hybrids was synthesized and its anticancer activity was assessed against 5 human tumor cell lines.⁹⁶ Among the synthesized compounds, hybrids 127 and

Fig. 79 Benzimidazole-quinazoline hybrids.

Fig. 80 Nitrogen containing analogs of acetogenins.

128 exhibited good anticancer activity, having the IC_{50} value between 2.01 and 7.01 μM and 1.94 and 3.46 μM , respectively. SAR studies further showed that in compounds **127** and **128**, 7-phenyl ring of the pyrazolo [1,5- α] pyrimidine was substituted with 3,4,5-trimethoxy, 4-fluoro, and 4-methoxy groups, which resulted in significant anticancer activity against 5 human cancer cell lines (A549, HeLa, MCF-7, HF2a, and ACHN) (Fig. 81). Novel isoflavene-propranolol hybrids were synthesized and evaluated as antitumor agents.³ Among the hybrids,

compounds **129** and **130** exhibited remarkable activity against the SHEP and MDA-MB-231 cell lines. SAR showed that substitution of an isoflavene scaffold with a 1-isopropyl amine-2-propanol side chain resulted in enhancement of the anti-proliferative and anti angiogenic properties (Fig. 82). Suthar *et al.*⁹⁷ synthesized novel quinolone-linked thiazolidine-4-one hybrids and evaluated them as antiinflammatory and anti-cancer agents. These hybrids were found to bind the active site NF-KB (which regulates genes involved in cancer and inflammation) for its suppression. Among the synthesized hybrid compounds, **131** and **132** showed remarkable activity against B7-549, HeLa, colon-205, and ACHN human cancer cell lines, which was attributed to the augmentation of apoptosis and NF-KB inhibition (Fig. 83).

Different groups of hybrids were synthesized by linking chromone-pyrimidine, chromone-indolinone, chromone-pyrazole, indole-pyrimidine, indole-indolinone, and indole-pyrazole

Fig. 81 Pyrazolopyrimidine linked aminobenzothiazole hybrids.

Fig. 84 Indole, pyrazole, chromone and pyrimidine based hybrids.

moieties.⁹⁸ Among the synthesized hybrids, compounds **133**, **134**, **135**, and **136** showed activity against tumor cell lines. SAR studies showed that the substitution of benzyl/2,6-dichlorophenyl/2,6-dichlorobenzyl groups with indole/indolinone moiety is responsible for an increase in the anticancer activity (Fig. 84). Quinazolinone, a natural product with a wide range of biological activities, is known to have inhibitory effects on tubulin polymerization and possesses anticancer activity. The *cis*-restricted analogues of

CA-4 (isoxazoline/isoxazoles) also possess anti-tubulin activity. Thus, a series of 2,3-dihydroquinazoline-linked 3,5-diaryl-isoxazoline/isoxazole hybrids were synthesized.⁹⁹ Among the hybrids, compound **137** exhibited remarkable activity against 18 human cancer cell lines. The mode of action of this compound was G2/M cell cycle arrest and inhibition of B1 and CDK1 (Fig. 85). Solomon *et al.*¹⁰⁰ synthesized a series of isatin scaffold-based hybrids of 4-piperaziny quinolone and evaluated it against two

Fig. 88 4-Arylidene curcumin analogs.

breast cancer cell lines: MDA-MB468 and MCF-7. The compounds were also evaluated against the non-cancer cell lines 184B5 and MCF10A. Among the synthesized 4-piperazinoyl quinolone-linked isatin hybrid compounds, **138** and **139** showed remarkable activity against MCF cancer cells by inducing apoptosis (Fig. 86).

A novel series of 2,4'-bis substituted diphenylamines was synthesized and evaluated for EGFR tyrosine kinase inhibitor activity. Compound **140** was found to be the most potent inhibitor with 98% inhibition at 10 μM (Fig. 87).¹⁰¹ A series of curcumin analogs was synthesized and evaluated for anticancer activity.¹⁰² The results of cell growth inhibition assays showed that compound **141** effectively decreased the growth of a panel of lung cancer cells at sub-micromolar concentrations. This compound was found to significantly inhibit NF- κ B activity as compared to the parent compound curcumin. This compound also reduced the tumorigenic potential of cancer cells in a clonogenic assay (Fig. 88). Various substitution patterns for aryl-sulfoanilides were identified through SAR studies, which were mediated by the partial depletion of intracellular Ca^{2+} stores.¹⁰³

Fig. 89 Arylsulfoanilide-oxindole hybrids.

The substitution patterns resulted in development of a potent arylsulfoanilide-oxindole hybrid **142** that showed micromolar activity against lung cancer cells in a growth inhibition assay (Fig. 89).

The molecular hybridization technique was used to design a new series of pyrazole-quinoline-pyridine hybrids.¹⁰⁴ The compounds were synthesized using a base-catalyzed cyclocondensation reaction and tested for EGFR enzyme inhibitory activity. Compound **143** emerged as the most potent anticancer agent since it was bound to the active pocket of EGFR *via* three hydrogen bonds and one π -cation (Fig. 90). Moreover, two pharmacophores, the acrylcinnamide skeleton and α -bromoacryl moiety, were combined together to synthesize a series of novel antiproliferative agents.¹⁰⁵ The new derivatives were tested against a panel of seven human cancer cell lines. The SAR studies confirmed that compound **144** slightly increased the ROS production in HeLa cells and decreased the glutathione content in the treated cells. It was also observed that only thiol-containing antioxidants were able to protect the cells from induced cell death (Fig. 91). The hybridized 5-hydroxypyrrolidones were synthesized by reacting butenolides with ethanolic amines.¹⁰⁶ On testing these compounds for anticancer activity *in vitro*, compound **145** exhibited the most potent anticancer activity against breast cancer cells. It was revealed from preliminary studies that the potency of this compound was due to ROS generation and activation of p38, which results in apoptosis of cancer cells (Fig. 92). Li *et al.*¹⁰⁷ synthesized a novel series of 4-pyrazolyl-1,8-naphthalimide derivatives and evaluated them for *in vitro* anticancer activity. When compared to the standard drug amonafide, compounds **146** and **147** showed better cytotoxic activity against MCF-7 cells with the IC_{50} values of 0.51 μM and 0.79 μM , respectively. UV-vis, fluorescence, and circular dichroism (CD) spectroscopies were used to study the DNA-binding properties of these compounds. The results suggested that compound **147** exhibited a middle binding affinity with CT-DNA (Fig. 93).

Fig. 90 Pyrazole-quinoline-pyridine hybrid.

Fig. 91 Arylcinnamide hybrid derivatives.

Fig. 92 Butenolides and polyfunctional pyrrolinones.

Sharma *et al.*¹⁰⁸ synthesized a novel series of purine-benzimidazole hybrids through nucleophilic substitution at the C-6 position of the purine ring with versatile cyclic amines at the C-2 position. On evaluating the novel compounds against 60 human tumor cell lines at one dose concentration level, compound **148** was found to be 1.25 times more active than the standard

60 Human Cancer Cell Lines
GI₅₀ = 18.12 mM

Aurora-A Kinase Inhibitor
IC₅₀ = 0.01mM

Fig. 94 Purine-benzimidazole hybrid compound.

control 5-FU, having a GI₅₀ value of 18.12 μM. This compound was also a selective inhibitor of Aurora-A kinase inhibitors with an IC₅₀ value of 0.01 μM (Fig. 94). Zayed *et al.* synthesized several novel fluorinated quinazolinone-sulphonamide derivatives and evaluated them for cytotoxic activity. The anticancer activities were determined by *in vitro* MTT assay using a three-cell-line panel consisting of lung cancer cells, breast cancer cells, and normal kidney cells. Compound **149** exhibited significant anticancer activity, and the toxicity levels were also low as compared to those of the standard drug methotrexate, with an IC₅₀ value of 2.51 μM on the NCI cell line (Fig. 95).¹⁰⁹

Histone lysine specific demethylase 1 (LSD1) was used as an anticancer drug target for the synthesis of a novel series of pyrimidine-thiourea hybrids.¹¹⁰ Compound **150** containing a terminal alkyne appendage was the most potent and selective LSD1 inhibitor *in vitro* since it exhibited strong cytotoxicity against LSD1 over-expressed gastric cancer cells. When the drug was orally administered, it showed a marked inhibition of cell migration without significant side effects (Fig. 96). A novel series of combretastatin-nocodazole hybrids were synthesized and evaluated for anticancer activity.¹¹¹ The conjugates were prepared by replacing the thiophene ring in nocodazole moiety with a substituted phenyl ring from the combretastatin moiety. The synthesized compounds were tested as tubulin polymerization inhibitors and antiproliferative agents against the human lung cancer cell line A-549. Compound **151** was found to

Fig. 93 Pyrazol-naphthalimide derivatives.

Fig. 95 Synthesis of fluorinated quinazolinone-sulphonamide hybrid compound.

Fig. 96 Pyrimidine–thiourea hybrid.

Fig. 97 Novel hybrid nocodazole analogue.

be most potent in both assays (Fig. 97). Eldehna *et al.*¹¹² synthesized three different sets of isatin–pyridine hybrids and evaluated them for anti-tumor activity against HepG2, A549, and MCF-7 cancer cell lines. Discovery Studio 2.5 software was used for the analysis of quantitative–structure activity relationship (QSAR) studies. The results revealed that compound **152** was the most active hybrid against HepG2, whereas compound **153** exhibited equal potency as compared to the standard drug doxorubicin (Fig. 98).

The development of the first chimeric c-Src kinase and HDAC inhibitor was described on the basis of synergism observed between a selective c-Src kinase inhibitor with an HDAC inhibitor. Further studies explored the high potency of the chimeric inhibitor **154** against cancer cell lines. This technique proved to be more efficacious than a dual-targeting strategy using discrete c-Src and HDAC inhibitors. The SAR studies described that the activity was due to the presence of a 1,5-triazole moiety synthesized using a ruthenium-mediated cycloaddition reaction (Fig. 99).¹¹³ As is well-known, the drugs that act upon multiple targets are far more superior to the single-target drugs provided the side effects are fewer. By exploring this basic idea, Guerrant *et al.*¹¹⁴ synthesized novel dual-acting histone deacetylase and topoisomerase II

Fig. 99 Chimeric c-Src kinase and HDAC inhibitor.

Fig. 100 Histone deacetylase and topoisomerase II dual-acting inhibitor.

inhibitors. The source for the derivatization of these dual-acting agents originated from suberoylanilide hydroxamic acid (SAHA) and anthracycline daunorubicin, prototypical histone deacetylase (HDAC), and topoisomerase II (Topo II) inhibitors. Compound **155** was found to inhibit HDAC and Topo II in both cell-free as well as whole-cell assays. The compound also inhibited the proliferation of representative cancer cell lines (Fig. 100). A novel series of dual acting compounds was synthesized to inhibit the effect of histone deacetylase (HDAC) and 3-hydroxy-3-methyl-glutaryl coenzyme A reductase (HMGR) enzymes.¹¹⁵ The inhibition was induced by introducing a chelating hydroxamate group with zinc ion at the active site of HDAC. The thus formed statin hydroxamic acid **156** showed most promising anticancer activity against HDACs and HMGR

Fig. 98 Isatin–pyridine hybrid compounds.

Fig. 101 Histone deacetylase and HMG-CoA reductase inhibitor.

with the IC_{50} values in the nanomolar range, without causing toxicity to the normal cells (Fig. 101).

A novel series of histone deacetylase inhibitors (HDACi) was synthesized by merging with either an antagonist or an agonist of the estrogen receptor (ER).¹¹⁶ The compounds were selectively active against breast cancer as they significantly inhibited HDAC at nanomolar concentrations by either agonizing or antagonizing ER α and ER β . Basically, two types of hybrid conjugates were synthesized: ethynylestradiol-HDACi conjugates (EED-HDACi) **157** and tamoxifen-HDACi conjugates (Tam-HDACi) **158**. The ER antagonist activities of Tam-HDACi were identical to those of tamoxifen, whereas EED-HDACi conjugates exhibited ER agonist activities as compared to the parent ethynylestradiol. The *in silico* docking analysis revealed that Tam-HDACi conjugates were more potent and selective against MCF-7 cancer cell lines than MDA-MB-231, DU145, and Vero cancer cell lines (Fig. 102). A novel series of curcumin-thalidomide hybrids was synthesized for the treatment of

human multiple myeloma (MM) and biologically characterized against MMIS, RPMI8226, U266 (human multiple myeloma), and A549 (human lung cancer) cells.¹¹⁷ The results revealed that compounds **159** and **160** were highly effective against all the human MM cell lines. The mechanistic studies explained that these compounds induced the production of ROS and caused G1/S arrest, leading to apoptosis and cell death. These compounds also exhibited inhibitory effects on NF κ B activation in A549 cells (Fig. 103). Manohar *et al.* synthesized novel molecular hybrids of 4-aminoquinoline and triazine as potential anticancer agents. Among the synthesized compounds, **161** and **162** were significantly active against NCI 60 human tumor cell lines. The results suggested that compound **161** activated caspase 8 and 9 but did not cause migration of phosphatidylserine, DNA fragmentation, and effector caspase activation. Compound **162** exhibited significant migration of phosphatidylserine that indicated cell apoptosis. This compound also activated caspase 9, but was unable to activate caspase 8. Furthermore, neither DNA fragmentation nor activation of effector caspases was observed (Fig. 104).¹¹⁸

Thiourea derivatives have been known to exhibit excellent anticancer activity. The studies also suggest that benzene-sulfonamide derivatives also possess apoptotic properties. To further explore the tumor inhibiting properties of these compounds, both moieties were incorporated together to develop a novel series of hybrid compounds. Structural analysis was carried out on the basis of elemental analysis, IR, 1H -NMR, ^{13}C -NMR, and mass spectral data. Compounds **163**, **164**, **165**, and **166** were found to be most active against all cell lines

Fig. 102 Estrogen receptor modulated histone deacetylase inhibitors.

Fig. 105 Highly active hybrid compounds of thioureido–benzenesulfonamides.

(except for breast cancer cell line), when compared with the standard drugs DCF and doxorubicin (Fig. 105). Molecular docking studies were used to explain the mechanism of action of these compounds. These studies suggested that the cytotoxic activity was due to their action as MK-2 enzyme inhibitors.¹¹⁹ A simple and convenient method was used to synthesize the novel hybrid compounds of quinazoline and sulfonamides. The *in vitro* anticancer evaluation of the synthesized compounds was

performed against four cancer cell lines, and **167** and **168** were found to be most active (Fig. 106). The results suggested that these hybrid compounds have a potential to be potent anti-cancer agents.¹²⁰ In a latest study, a newly developed ligand-free simple and inexpensive one-pot method was employed to design rosuvastatin-based novel indole derivatives. The reaction involved copper-catalyzed coupling-cyclization of rosuvastatin-based alkyne with *o*-iodoanilides. PEG-400, copper(I) iodide, and potassium chromate were also used to complete the reaction. The synthesized compounds were highly active against cancer cell lines. Furthermore, increase in p21 mRNA

Fig. 106 Synthesis of novel quinazoline–sulfonamide hybrids.

Fig. 107 Cu-catalyzed rosuvastatin–indole derivatives.

expression and apoptotic effects in the embryos of zebrafish were also observed. The design of rosuvastatin-indole hybrid compounds **169** is shown in Fig. 107.¹²¹

10. Future perspective

The hybrid anticancer agents have been proven to be a boon for pharmaceutical industries. The design of these drugs is not only efficacious but also cost-effective. Imagination and creativity along with skills are necessary to construct a new hybrid drug. The research in this field is still ongoing throughout the world. The future hybrid drugs should be designed in a way that they can tackle more than one type of cancer by showing multi-target effect with less toxicity. Moreover, the techniques such as use of blended or fully integrated chemical structures and formation of vectorized anticancer hybrids may prove to be useful. It will be better to synthesize the drugs that release its active ingredients at the site of action for more specific results. The design of drug formulations can also be changed in a way that the carrier molecules show high affinity for its cognate receptors. A number of studies are being carried out in this field, and in coming days, we will surely see advancement in the design and discovery of novel hybrid anticancer molecules.

11. Conclusion

This review article summarized the intellectual advances in designing anticancer hybrids *via* utilizing molecular hybridization technique. Literature survey assigns the merits of molecular hybridization to novel hybrids that have been designed and discovered from the fusion of two or more active moieties or pharmacophore units. Molecular hybridization results in compounds with changed selectivity profile, less toxicity, dual actions, and new molecular scaffolds. In most of the studies, the main reason for using molecular hybridization is for targeting tubulin as microtubules play a critical role in cellular functions such as cell division, intracellular transport, cell death, and cell shape. Thus, in different hybrid designs, one of the active moieties is microtubule inhibitor such as chalcones, combretastatin, and colchicines, and promising results have been obtained. Isatin and coumarin, the heteroaryl-based drugs, were also reported with inhibitory activity for the pyrrolo [2,1-c][1,4]benzodiazepine (PBD). The DNA interactive anti-tumor antibiotics obtained from streptomyces species hybrids were also synthesized that resulted in significant activity. Overall, the scope of molecular hybridization is quite broad for medicinal chemists around the globe. This technique has been utilized to synthesize multi-target drugs and tackle complex diseases such as cancer.
