Iron oxide nanoparticles functionalized with nisin for rapid inhibition and separation of *Alicyclobacillus* spp.

Zihan Song, Yahong Yuan, Chen Niu, Lu Dai, Jianping Wei and Tianli Yue*

Alicyclobacillus acidoterrestris can spoil various fruit juices, and tools to reduce the impact of this contaminant are urgently needed. Here, we describe a novel therapeutic approach in which iron oxide nanoparticles (IONPs) were conjugated with the known antibiotic nisin (IONPs–nisin). The size, crystalline nature, magnetic characteristics and surface charge of the nanoparticles were characterized with transmission electron microscopy (TEM), X-ray diffraction (XRD), vibrating sample magnetometry (VSM) and Zetasizer Nano ZS (Zeta). The average diameter of the IONPs was 30 ± 7 nm. The TEM and XRD data indicated that the IONPs were very spherical magnetic particles with a single crystalline phase. The VSM study showed that the IONPs were superparamagnetic with a saturation magnetization (MS) of about 33 emu g^{-1} . The IONPs had a negative charge of around -32.8 mV at pH 7.0. The optimal preparation of IONPs–nisin composites was at pH 7.0 with a 2 : 1 (IONPs : nisin) ratio for 1 h. FT-IR data confirmed conjugation of IONPs to nisin, and the composites retained 86.69% of their antimicrobial activity after storage for 7 days at 4°C and 83.46% after storage for 7 days at 25°C . The products retained their antibacterial activity after treatment at pH 2 to 11. The minimum inhibitory concentration (MIC) of IONPs–nisin composites against *A. acidoterrestris* DSM 3923 was 2.5 mg mL^{-1} of AAM medium (pH 4.2). Finally, we used the CFDA-SE leakage assay and scanning electron microscopy (SEM) to show that the IONPs–nisin inhibited target strains via pore formation in the membrane—this is the same as with nisin. These composites retained the features of both nisin and IONPs. The composites were easily separated from the sample via a magnet after being deployed as antimicrobials. To the best of our knowledge, this is the first report of an IONP–nisin composite with significant implications to the food safety community. These products might be useful tools for controlling spoilage due to *A. acidoterrestris*.

Introduction

Alicyclobacillus is a global challenge to food quality and can survive typical heat processing. It is the main cause of spoilage in a variety of fruit juices. Spoilage incidents due to *Alicyclobacillus acidoterrestris* have been found in apple juice,¹ mango juice,² pear juice³ and other acidic beverages.⁴ Strains are common in soil from the Orchard^{5–8} and contaminate the juice through a variety of unknown access routes. Most *Alicyclobacillus* species are both heat-resistant and acid-tolerant. They can grow from $20\text{--}75^\circ\text{C}$ with a pH range of 2 to 6.⁹ There are broad economic losses due to *Alicyclobacillus*,¹⁰ and new tools to control *Alicyclobacillus* spoilage are urgently needed.

Established antibacterial substances including natural and synthetic compounds as well as innovative methods including irradiation with electron, gamma beams, microwaves, high hydrostatic pressure and high pressure homogenization can inhibit *Alicyclobacillus*.^{11,12} One such novel approach is the

bacteriocins—natural antimicrobial agents with no off-target toxicity. One of the most common bacteriocin is nisin, which has been extensively studied and approved as a food additive.^{13–15}

To control *Alicyclobacillus acidoterrestris*, nisin has been used alone^{16,17} or in a variety of novel products: nisin-incorporated films,¹⁸ nisin synergistically interacting with Piperaceae extracts,¹⁹ nisin combined with sodium benzoate or potassium sorbate,²⁰ nisin combined with thermal treatments,¹⁵ and nisin combined with high pressure.²¹ Nevertheless, one study found that nisin can inhibit many human intestinal bacteria.²² To solve this, some recent reports have described nanomaterial conjugates of nisin that can inhibit resistant bacteria and then be easily separated from the food product.^{23,24}

Magnetic iron oxides are easily synthesized compounds with unique characteristics and widespread applications.²⁵ Magnetic IONPs are low cost, superparamagnetic, low toxicity, environmentally safe, easily magnetically separate, and biocompatibility.^{25,26} However, to the best of our knowledge, there is no report of IONPs being functionalized with nisin. Here, for the first time, we report the integration of magnetic iron oxide nanoparticles with nisin via electrostatic adsorption. The

College of Food Science & Engineering, Northwest A&F University, 712100 Yangling, Shaanxi, China. E-mail: yuetl305@nwsuaf.edu.cn; Tel: +86-29-87092492

complex not only conserves the effective inhibition of nisin towards *Alicyclobacillus*, but the magnetic nature of the nanoparticle facilitates easy separation. This product has strong activity against *Alicyclobacillus* and is temporally stable across a variety of pH challenges.

Results and discussion

Optimization of IONPs–nisin composites preparation conditions

Fig. 1 shows that interaction between IONPs and nisin was based on physical absorption—anionic IONPs were absorbed by the cationic nisin. The most important parameters were pH, reaction time, and proportion of IONPs to nisin.

The pH value was studied from 2.0–10.0, and the maximum inhibition occurred at pH 7.0 and 8.0 (Fig. 2a). The pH variation has an appreciable influence on the interaction between IONPs and nisin, which results from the rationale of the preparation of IONPs–nisin composites. Apparently, the inhibition activity has no significant difference between pH 7.0 and 8.0 taking the error range into account. Therefore, the optimal pH was selected as 7.0.

The optimal proportion of the IONPs and nisin in the process of the preparation of IONPs–nisin was investigated (Fig. 2b). As the proportion of nisin and IONPs increased from 1 : 0.5 to 1 : 2, the inhibitory zone diameters grew sharply. Although the proportion continuously increased to 1 : 4, there was no significant change. Therefore, 1 : 2 (nisin/IONPs) was selected.

The reaction time was varied from 0.5 h to 4 h. The goal was a short reaction time with good performance. Fig. 2c shows that

one hour was sufficient and offered satisfactory results. Therefore, 1 h was used for all subsequent studies.

Fig. 2d shows that the zone of inhibition of both IONPs–nisin composites and homologous supernatant vanished after the sixth formation of IONPs–nisin. Hence, the maximum adsorption proportion was 12 : 1 (IONPs : nisin).

Characterization of IONPs with/without nisin

TEM (Fig. 3a) shows the morphology and particle size of the IONPs with an average diameter of 30 ± 7 nm. The lattice planes corresponding to IONPs were analyzed by electron diffraction (Fig. 3b). Different ring diameters are shown in Fig. 3b indicating the different lattice planes of the IONPs. The fringe patterns demonstrated that the IONPs are single crystalline. Fig. 3c shows two adjacent planes on the IONPs surface. These were marked in the image and indicated a lattice separation of 0.296 nm and 0.253 nm, which corresponded to the (220) and (311) lattice planes (JCPDS card no. 19-0629). Fig. 3b and c show that the IONPs were mixed with no impurities.

XRD patterns of the IONPs are shown in Fig. 4. The diffractogram of the IONPs had peaks at 2θ of 30° , 35.6° , 43.3° , 57° and 62.7° corresponding to signals from the (220), (311), (400), (511) and (440) crystalline planes, respectively (JCPDS card no. 19-0629). According to the Debye–Scherrer equation, the average crystallite size of the IONPs calculated from the FWHM of the XRD peaks was ~ 30.29 nm, which agreed nicely with the TEM data.

Hysteresis loops of the IONPs were carried out at room temperature using vibrating sample magnetometry (VSM) to characterize the magnetic properties. Fig. 5 shows that the

Fig. 1 Schematic representation showing the synthetic procedure for the formation of nisin antimicrobials peptide attached IONPs.

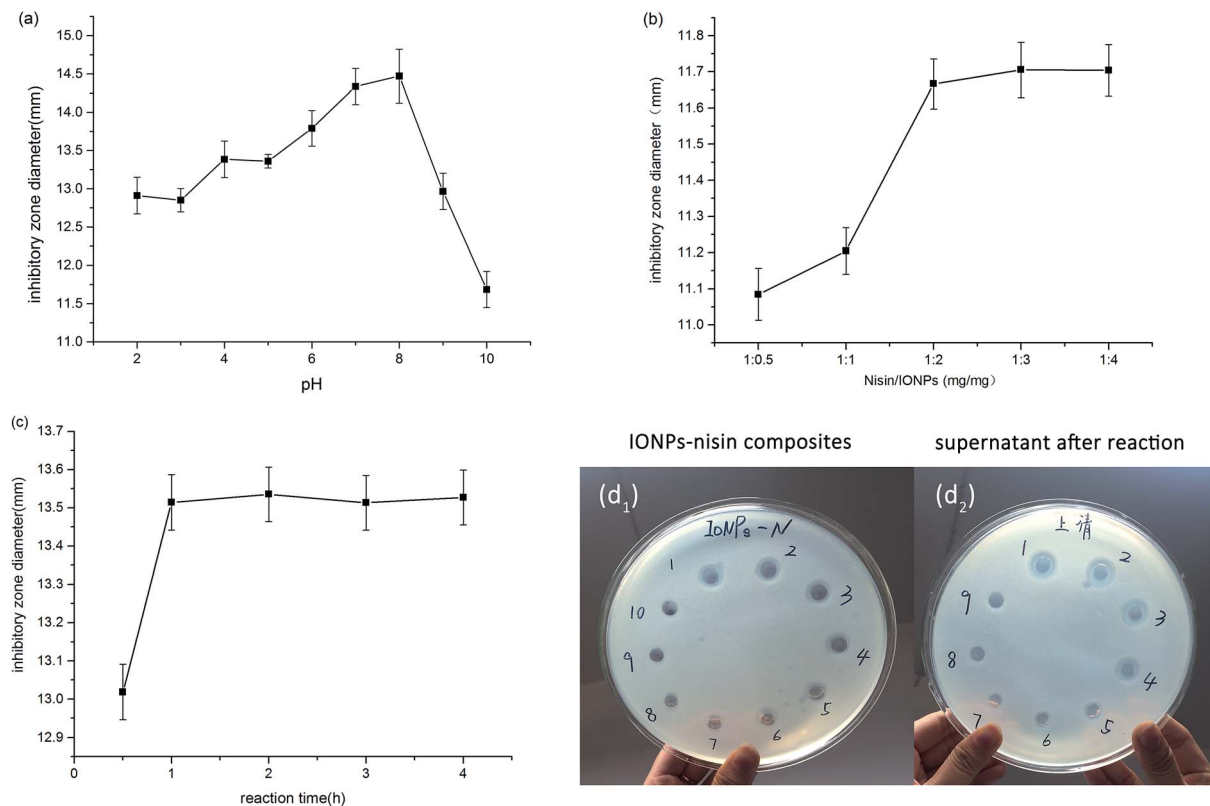

Fig. 2 Effect of (a) pH of the system, (b) the proportion of nisin and IONPs, (c) the reaction time on the preparation of IONPs–nisin composites. (d) Agar well diffusion assay to ascertain the maximum adsorption concentration of IONPs/nisin. 10 mg IONPs were added to nisin (1 mg mL^{-1}) to obtain IONPs–nisin composite followed by magnetic separation. This process was repeated 10 times, and 100 μL of the supernatant was reserved after each reaction. 1–10 (d_1) and 1–10 (d_2) represented the number of addition times.

saturation magnetization (M_s) was about 33 emu g^{-1} , and the S-shaped magnetic hysteresis loops of the IONPs exhibited zero remanence and coercivity, which indicated that the nanoparticles are superparamagnetic.

The zeta potential was carried out at pH 7.0 because the IONPs interact with nisin best at neutral pH. The IONPs had a negative charge of around -32.8 mV at pH 7.0 (Fig. 6) due to the charge-based synthesis of IONPs–nisin composites.

FT-IR was used to demonstrate the presence of nisin on the surface of the IONPs (Fig. 7). The spectrum of IONPs–nisin composites has a broad band at $\sim 3415 \text{ cm}^{-1}$ probably due to overlap of two different bands from the free amino groups of nisin and O–H stretching vibration of H_2O adsorbed on the surface of the Fe_3O_4 nanoparticles. The broad absorption bands at $\sim 1643 \text{ cm}^{-1}$ are due to the characteristic amide stretching vibrations. These were retained on IONPs–nisin the composites.

Antimicrobial activity of IONPs–nisin composites as a function of pH and thermal stability

Table 1 shows that the IONPs–nisin composites retained antibacterial activity after treatment at pH 2–11. The activity was reduced as the composite was treated at lower or higher pH. Specifically, there was no difference in inhibitory activity after treatment at pH 4.0–8.0 ($p > 0.05$), which retained the best ability to inhibit *A. acidoterrestris*. In addition, the inhibitory activity showed no difference when treated at extreme pH values

of 3.0, 9.0, 10.0, and 11.0. However, significant differences were observed after treatment at pH 2.0 ($p < 0.05$). This was due to the dissociation of IONPs–nisin composites at lower pH.

Table 1 also shows that IONPs–nisin composites were heat-stable. There was no significant difference in inhibitory activity after heat treatment even up to 60 min ($p > 0.05$). These features are critical for practical applications of this technology. *A. acidoterrestris* is common in areas without good access to cold storage, and these stabilizing features of the IONP make this approach even more significant.

Storage study

Fig. 8 illustrates the antimicrobial activity of IONPs–nisin composites after storage at 4°C and room temperature (25°C). The remaining antimicrobial activity was about 86.69% after storage for 7 days at 4°C and 83.46% after storage for 7 days at 25°C . As a result, the IONPs–nisin composites can be conveniently stored even at room temperature.

Minimum inhibitory concentration (MIC)

The MIC of IONPs–nisin composites against *A. acidoterrestris* DSM 3923 was 2.5 mg mL^{-1} of AAM medium (pH 4.2). The result was approximately the same as the MIC value of nisin reported in the literature.¹⁷

Fig. 3 (a) TEM images, (b) selected area electron diffraction (SAED) pattern, (c) single crystallite lattice fringe pattern.

Fig. 4 XRD patterns of IONPs.

Fig. 5 Hysteresis loops of the IONPs at room temperature.

CFDA-SE leakage assay

A CFDA-SE leakage assay was carried out to demonstrate the effect of permeabilising the cytomembrane *via* IONP–nisin composites.

Fig. 9 shows leakage of CFDA dye after treating with both IONP–nisin composites and nisin. The data indicated membrane destruction. More dye is present with increased reaction time and more antibacterial substances. This trend was due to nisin as indicated by the controls. The IONP–nisin

destroyed the bacterial membrane and caused leakage of the cytoplasmic concentrates to ultimately kill the strain.

Scanning electron microscope (SEM)

A SEM study was done to identify changes in the DSM 3923 after treatment with IONPs–nisin. The untreated DSM 3923 cells were smooth on the surface and had a normal cellular structure. These retained their integrated cell wall with no debris in the surrounding environment (Fig. 10a). After incubation with the

Fig. 8 Effect of the storage time at 4 °C and 25 °C on the antimicrobial activity.

IONPs-nisin for 1 h, an irregular and rough cell surface emerged. The cell wall was damaged with pores on the end and in the middle (Fig. 10b and c). There was extensive destruction of the cell morphology when DSM 3923 cells were treated with IONPs-nisin for 2 h (Fig. 10d). The treatment caused the membrane surface to collapse with disorganization of the bacterial cell leading to cell death.

Extensive studies have shown that the bactericidal mechanism of nisin is pore formation on the cell membrane of the target bacteria.²⁴ The SEM and CFDA-SE data show that the IONPs-nisin also disrupts the bacteria membrane similar to free nisin.

Experimental

Materials

Nisin and sodium dodecyl sulphate (SDS) were purchased from Sigma-Aldrich (USA). CFDA-SE Cell Proliferation Assay and Tracking Kit (CFDA-SE) was purchased from Enogene, China. Other common reagents were obtained from a local supplier including ferrous sulfate ($\text{FeSO}_4 \cdot 6\text{H}_2\text{O}$, 99%), ferric nitrate [$\text{Fe}(\text{NO}_3)_3$, 99%], triethylamine (99.5%), methanol (99%), sodium hydroxide (NaOH, 96%), hydrochloric acid (HCl, 37%) and phosphate buffer saline (PBS, pH 7.0).

Bacterial strains and antimicrobial activity assay

The bacterial strain was *A. acidoterrestis* DSM 3923, which was purchased from the German Resource Centre for Biological Material (DSMZ). The strain was propagated in the *Alicyclobacillus* spp. medium (AAM) and incubated at 45 °C with a stirring rate of 120 rpm for 18 h. AAM broth contained yeast extract (2.0 g), glucose (2.0 g), $(\text{NH}_4)_2\text{SO}_4$ (0.4 g), $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ (1.0 g), CaCl_2 (0.38 g), KH_2PO_4 (1.2 g), distilled water (1 L) (pH 4.2).

The antimicrobial activity of nisin-IONPs composites was assayed *via* the agar well diffusion method with minor modifications.²⁷ Briefly, the assay plates consisted of two layers. The bottom layer was covered with 10 mL of 2% sterile agar. After agar solidification, sterile Oxford cups (diameter 9 mm) were placed lightly on the samples. Then, 10 mL AAM soft agar (1% agar) mixed with approximately 10^6 CFU mL^{-1} freshly grown indicator strain cells of *A. acidoterrestis* DSM 3923 was poured on the upper layer. Oxford

Fig. 10 Morphological changes of *A. acidoterrestris* DSM 3923 after treatment with IONPs-nisin composites (a) untreated control, (b) and (c) treated for 1 h, (d) for 2 h.

cups were removed after solidification, and 100 μL of the specimen was added to each well. The plates were stored at 4 °C for 2 h to allow sufficient sample diffusion. The samples were then incubated at 45 °C for 18 h, and the zone of inhibition was measured to assay the antimicrobial activity.

Synthesis of iron oxide nanoparticles (IONPs)

The IONPs were prepared *via* an earlier known method.²⁸ The most easily performed method uses co-precipitation based on the following mechanism: $\text{Fe}^{2+} + 2\text{Fe}^{3+} + 8\text{OH}^- \rightleftharpoons \text{Fe}(\text{OH})_2 + 2\text{Fe}(\text{OH})_3 \rightarrow \text{Fe}_3\text{O}_4 \downarrow + 4\text{H}_2\text{O}$.²⁵ Briefly, aqueous FeSO_4 and

Fe(NO)₃ solution (0.1 M each) were mixed at 1 : 1. The mixture was then stirred for 30 min followed by the addition of 3.0 mM SDS with stirring for another 30 min. Then, triethylamine (~5% v/v) was added dropwise under vigorous stirring for 2 h. Before adding the base, the pH of this system was kept at 2.0–3.0. The entire process was done under stirring to assure homogeneity. The color of the suspension turned from dark brown to complete black after 5 h of vigorous stirring. The magnetic precipitates were washed with several rounds of sonication using MilliQ water and methanol to remove unreacted chemicals and other impurities. The particles were vacuum freeze-dried overnight to yield IONPs.

Optimization of IONPs–nisin composite preparation conditions

A 1 mg mL^{−1} solution of nisin (10 000 IU mL^{−1}) was prepared in sterile phosphate buffer with pH values of 2–10. Then, different amounts of IONPs (0.5 mg mL^{−1}, 1 mg mL^{−1}, 2 mg mL^{−1}, 3 mg mL^{−1} and 4 mg mL^{−1}) were added to the different pH values. After incubation at 4 °C (0.5 h, 1 h, 2 h, 3 h and 4 h) under mild shaking, the solution was separated magnetically using a horse-shoe magnet. The pelleted IONPs–nisin composites were washed twice with sterile phosphate buffer (pH 7.0) and resuspended in the same buffer. The antimicrobial activity was measured using the agar well diffusion method to determine the best nisin–IONPs composition.

To confirm the maximum adsorption of IONPs/nisin, a 10 mL stock solution of nisin (1 mg mL^{−1}) was prepared in phosphate buffer (pH 7.0, 0.1 M). Then, 10 mg IONPs were added to the nisin solution and incubated for 1 h under mild shaking to form IONPs–nisin composites followed by magnetic separation of the composites. This was repeated 10 times, and 100 µL of the supernatant was reserved after each reaction. Both IONPs–nisin composites and the homologous supernatants were used in antimicrobial assays *via* the agar well diffusion method. The maximum adsorption proportion was calculated by observing the zone of inhibition.

Materials characterization

The IONPs were characterized with multiple techniques. Transmission electron microscopy (TEM, JEOL 2000F, Japan) with 200 kV accelerating voltage was used to observe the morphology and particle size. The magnetic properties were measured using vibrating sample magnetometry (VSM-7307, Lake Shore, USA). A Zetasizer Nano ZS (90, Malvern, UK) was used to investigate the zeta potential of the IONPs. X-ray diffraction (XRD) measurements used X-ray diffractometer (XRD, BRUKER D8 ADVANCE, German). Fourier transform infrared spectrometer (FT-IR, Vetex70, BRUKER, German) was used to confirm the chemical composition of IONPs–nisin.

Antimicrobial activity of IONPs–nisin composites

Sensitivity to pH and temperature. To investigate the pH stability, IONPs–nisin composites were added into the following buffers (20 mM): glycine–HCl (pH 2.0), citric acid phosphate (pH 3.0, 4.0, 5.0 and 6.0), PBS (pH 7.0), Tris–HCl (pH 8.0 and 9.0)

and glycine–NaOH (pH 10.0, 11.0 and 12.0). After 2 h of incubation at 4 °C, the IONPs–nisin composites were separated by a magnet and resuspended in the PBS (pH 7.0). The antimicrobial activity of the composites was again determined *via* the agar well diffusion method.

To investigate the heat stability, IONPs–nisin composites were resuspended in PBS (pH 7.0) and treated at 40 °C, 60 °C, 80 °C and 100 °C in a water bath for 60 min. After each treatment, the IONPs–nisin composites were immediately cooled in ice water, and the residual activity was tested with the agar well diffusion method mentioned before.

Storage study

The IONPs–nisin composites were stored at 4 °C for 7 days. During storage, the samples were withdrawn periodically (days 1, 3, 5, and 7), and the residual activities were assayed by agar well diffusion method. The inhibitory zone diameters of the treated samples and the control samples were both measured. The control samples were defined as 100% and the other samples were compared to this baseline.

Minimum inhibitory concentration (MIC)

IONPs–nisin composites were serially diluted in sterile PBS (pH 7.0). Thereafter, 10 µL diluted solution was mixed with 90 µL medium (AAM, pH 4.2) containing 10⁶ CFU mL^{−1} *A. acidoterrestris* DSM 3923. The mixture was added to 96-well microtiter plates and cultivated at 45 °C for 24 h. The controls were 10 µL sterile PBS (pH 7.0) mixed with bacterial culture under the same conditions. To exclude the interference of IONPs–nisin absorbance, the microtiter plate was placed in the field of a horseshoe magnet for 1 min to assemble the magnetic composites. Absorbance measurements of the mixture were carried out on a Microplate Reader (BIO-RAD, America) at 600 nm with three independent experimental samples. The MIC values were determined as the lowest concentration that resulted in an OD₆₀₀ reading of <0.1.

CFDA-SE leakage assay

We used the carboxy fluorescein diacetate succinimidyl ester (CFDA-SE) leakage assay to demonstrate the cell membrane-directed antibacterial activity of IONPs–nisin composites.²⁴ The *A. acidoterrestris* DSM 3923 cells were incubated for 12 h and were collected by centrifugation at 8000 rpm for 8 min. After washing twice with sterile PBS, the cell pellet was resuspended in 10 mL labeling buffer with 20 µL of CFDA-SE. This was incubated for 20 min at 37 °C in the dark. The cells were subsequently washed three times with PBS and centrifuged at 8000 rpm for 8 min.

After staining, 10⁶ CFU mL^{−1} labeled cells were treated with IONPs–nisin composites and nisin solutions of varying concentrations at 45 °C for 1, 2, or 3 h. The cells were also treated with PBS buffer under the same conditions as control samples. Then, cell free supernatants of all samples were collected by centrifuging at 8000 rpm for 15 min. The fluorescence of the supernatant was measured with fluorescence spectrophotometry (F-7000, HITACHI, Japan) with a slit width of 5 nm, an excitation wavelength of 488 nm, and an emission

wavelength of 518 nm. The fluorescence of the control was subtracted from the samples. This was expressed as the maximum nisin activity (100%).

Scanning electron microscope (SEM)

SEM was used to observe the morphological changes of *A. acidoterrestris* DSM 3923 strain (10^7 CFU mL⁻¹) after treatment by IONPs–nisin composites and incubation at 45 °C for 1 h and 2 h respectively. After magnetic separation of IONPs–nisin composites, the target cells were collected by centrifugation and fixed with 2.5% (v/v) glutaraldehyde at room temperature for 2 h. The cells were then washed three times for 10 min each time with PBS (pH 7.2, 0.1 M). Dehydration used successively treatments with ethanol: 30%, 50%, 70%, 80% and 90% ethanol for 10 min each. This was followed by 100% ethanol twice for 10 min and isoamyl acetate to replace ethanol. After drying with CO₂ for 3 h and coating with gold (10 mM), the cells were observed with SEM (S-4800, Hitachi, Japan).

Statistical analysis

All experiments were repeated in triplicate. ANOVA and Duncan's multiple range test were used to analyze the data; $p < 0.05$ was considered statistically significant.

Conclusions

In this work, a charge-based approach was successfully used to obtain IONPs–nisin composites. The IONPs are ferromagnetic in nature and can be rapidly separated by an external magnetic field. FT-IR analysis confirmed the existence of nisin on the surface of IONPs. The pH, thermal and storage stability of IONPs–nisin composites were held consistent with nisin. Moreover, the composites combined the advantages of bactericide and magnetic separation. The primarily antimicrobial mechanism of the composites might be pore formation in the cell membrane. The future work will focus on the interaction analysis between IONPs–nisin composites and food ingredients such as protein, lipid, oxidative product and carbohydrates. More systematic research should be done before the practical application for the food sector.
