### 1. Introduction

Owing to their advantages on lifespan and energy density, rechargeable lithium-ion batteries have attracted increasing interest due to their wide application in energy storage systems (ESSs) and electric vehicles (EV/HEV/PHEV).<sup>1-5</sup> The increasing demands for high-energy or high-power batteries are driving the research interest in electrode materials with a large specific energy.<sup>6-8</sup> Unfortunately, graphite or carbon-based materials with low theoretical specific capacity (*ca.* 372 mA h  $g^{-1}$ ) are not highly desirable for the high energy-density batteries.9,10 In contrast, binary metal oxides, such as ZnFe<sub>2</sub>O<sub>4</sub>, NiFe<sub>2</sub>O<sub>4</sub>, ZnMn<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>, seem to be a more promising alternative because of their high theoretical capacity and high redox activity.11-14 Among the numerous investigated binary metal oxides, spinel nickel cobaltite (NiCo<sub>2</sub>O<sub>4</sub>) has been regarded as a promising electrode composite due to the high specific capacity (890 mA h  $g^{-1}$ ), environmental friendliness and low cost.15,16 However, NiCo2O4 also suffers from sluggish reaction kinetics and drastic volume change during lithium insertion/ extraction processes, resulting in the structure deterioration (pulverization or aggregation) and consequent severe decay in capacity.17,18 To address above significant drawbacks, lots of

## Hierarchical flower-like NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> heteronanosheets as anodes for lithium ion batteries

Wei Chen,<sup>abc</sup> Luya Wei,<sup>a</sup> Zhiya Lin,<sup>a</sup> Qian Liu,<sup>a</sup> Yue Chen,<sup>a</sup> Yingbin Lin<sup>b</sup>\*<sup>abc</sup> and Zhigao Huang<sup>abc</sup>

Flower-like NiCo<sub>2</sub>O<sub>4</sub> consisting of nanosheets are synthesized by hydrothermal technique and subsequently surface-modified with a TiO<sub>2</sub> ultrathin layer by a hydrolysis process at low temperature. It is found that NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> exhibits superior electrochemical performances over NiCo<sub>2</sub>O<sub>4</sub> in terms of rate capability and cyclability. After 60 cycles at 100 mA  $g^{-1}$ , NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> showed 78% capacity retention compared with 57% for bare NiCo<sub>2</sub>O<sub>4</sub>. Analysis from the electrochemical measurements indicates that the improved electrochemical performances of NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> might be attributed to a higher lithium diffusion rate, smaller charge-transfer resistance and more structural stability. Kelvin probe force microscopy measurements reveal that NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> has a lower work function than those of the pristine one, which help to facilitate electron transfer in composites. In addition, the electric field between NiCo<sub>2</sub>O<sub>4</sub> and TiO<sub>2</sub> resulting from the difference in work functions is also expected to enhance the electrochemical performances.

effective strategies have been implemented and surfacemodification has been proved to be an effective way to improve electrochemical performances, which not only suppresses the formation of excessive amounts of SEI but also stabilizes structure of the active materials.19 Kou et al.19 reported that Al<sub>2</sub>O<sub>3</sub>-coated NiCo<sub>2</sub>O<sub>4</sub> exhibits improved cyclability with a reversible capacity of 395 mA h g<sup>-1</sup> after 50 cycles. Titanium oxide (TiO<sub>2</sub>) has been investigated extensively as an anode material, whose volume expansion is less than 4% during the lithium insertion processes.20,21 The low volume expansion would be desirable for adhesion of the coating to the matrix materials, resulting in the enhanced structural stability and a excellent cycle life. On the other hand, TiO<sub>2</sub>-coating layer acting as an interfacial barrier can also significantly enhance cyclic performances by suppressing the exothermic reaction between the active material and the electrolyte.

In view of all the above, we employ hydrolysis technique to coat  $TiO_2$  on flower-like  $NiCo_2O_4$  consisting of nanosheets at low temperature, and the effect of  $TiO_2$ -coating on the kinetics of  $Li^+$  insertion/extraction is systematically investigated. It is found that the high capacity of  $NiCo_2O_4$  and the excellent stability of  $TiO_2$  as well as the hierarchical structure make the designed composite demonstrate improved rate capability and cycling stability.

### 2. Experimental

#### 2.1 Preparation and characterization of anode materials

Flower-like NiCo<sub>2</sub>O<sub>4</sub> consisting of nanosheets are prepared by hydrothermal technique. All chemicals are purchased from

<sup>&</sup>lt;sup>a</sup>College of Physics and Energy, Fujian Normal University, Fujian Provincial Key Laboratory of Quantum Manipulation and New Energy Materials, Fuzhou, 350117, China. E-mail: yblin@fjnu.edu.cn; Fax: +86-591-2286-8132; Tel: +86-591-2286-8132 <sup>b</sup>Fujian Provincial Engineering Technology Research Center of Solar Energy Conversion and Energy Storage, Fuzhou, 350117, China

<sup>&</sup>quot;Fujian Provincial Collaborative Innovation Center for Optoelectronic Semiconductors and Efficient Devices, Xiamen, 361005, China

Aladin and used without further purification. In a typical synthesis, 6 mmol of Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and 12 mmol of  $Co(NO_3)_2 \cdot 6H_2O$  are thoroughly dissolved in 30 ml of deionized water and 30 ml of absolute ethanol, followed by stirring until a light pink solution is formed. Then, 0.1 g of polyvinyl pyrrolidone (PVP) is added to the above aqueous solution under continuous stirring. After vigorous stirring for another 60 min, the resulted mixture is transferred into a 100 ml Teflon-lined autoclave, sealed and maintained at 180 °C for 36 h. After being cooled to room temperature, the precipitates are collected through centrifugation, washed several times with de-ionized water and ethanol, dried at 100 °C overnight under vacuum. The obtained precursors (Ni-Co-O) are calcinated at 450 °C for 5 h in air to get flower-like NiCo2O4 powders. NiCo2O4@TiO2 composites are synthesized by a hydrolysis process at low temperature using tetrabutyl titanate (Ti(OC<sub>4</sub>H<sub>9</sub>)<sub>4</sub>) and Ni-Co-O powders as precursors. 0.23 g of the as-prepared Ni-Co-O precursors are dispersed in 20 ml of absolute ethanol and 1 ml of deionized water under vigorous stirring at 4 °C. Then, 10 ml  $10^{-3}$  M Ti(OC<sub>4</sub>H<sub>9</sub>)<sub>4</sub> ethanol solution is added dropwise into above solution. After stirring at 4 °C for another 24 h, the resulting precipitates are isolated by centrifugation, dried at 60 °C for 12 h and subsequently sintered at 450 °C for 5 h to obtain flower-like NiCo2O4 surface-modified with TiO2. The schematic illustration of the synthesis process for the NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> characterized anode materials is shown in Fig. 1.

The crystalline structure of the as-synthesized powders is characterized by X-ray diffraction (XRD, Rigaku MiniFlex II) using CuK<sub> $\alpha$ </sub> radiation ( $\lambda = 0.15405$  nm). Thermo-gravimetric analysis (TGA) analysis are carried out using

thermogravimetric analysis (TGA, Netzsch STA449F3) from 30 to 600 °C at a heating rate of 5 °C min<sup>-1</sup> under an air atmosphere. Scanning electron microscope (SEM) images are obtained on a Hitachi SU8010 field-emission scanning electron microscope equipped with an energy-dispersive spectroscopy (EDS). The TiO<sub>2</sub> content in the composite is determined by inductively coupled plasma OES spectrometer (ICP). Raman scattering is carried out on a Horiba/Jobin Yvon Raman instrument using a 532 nm emission line. Nitrogen sorption isotherms are measured at 77 K using a Micromeritics Tristar 3020 analyzer. Specific surface areas of the as-prepared powders are calculated according to the Brunauer–Emmett–Teller (BET) method. The pore size distribution is determinated according to the theory of Barrett, Joyner and Halenda (BJH).

The surface potentials of  $NiCo_2O_4$  and  $NiCo_2O_4$  (aTiO<sub>2</sub> are measured by Kelvin probe atomic force microscopy (KPAFM) (Bruker dimension ICON, Germany).

#### 2.2 Cell fabrication and characterization

The electrochemical performances of the as-fabricated samples are evaluated with CR2025-type coin cell and assembled in an argon-filled glove box ( $O_2$ ,  $H_2O < 1$  ppm). The working electrodes are prepared by coating anode slurries which are made up of 70 wt% active material (NiCo<sub>2</sub>O<sub>4</sub> or NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub>) with 10 wt% polyvinylidene fluoride (PVDF) and 20 wt% super-P in *N*-methyl-2-pyrrolidone. The anode slurry is cast onto a copper current collector and dried in vacuum at 110 °C for 12 h to remove the residual solvent. A lithium foil is used as the reference and counter electrodes, Cellgard 2300 microporous polyethylene membrane as separator. The electrolyte consists of 1 M

RSC Advances

LiPF<sub>6</sub> in a mixture of ethylene carbonate (EC) and dimethyl carbonate (DMC) (1 : 1 in volume). The cells are galvanostatically charged and discharged on a multichannel battery testing system (Land CT2001A, Wuhan, China) in the voltage range of 0.01–2.5 V. The cyclic voltammetry (CV) measurements are carried out using an Arbin instruments BT-2000 battery testing station, and the electrochemical impedance spectra of the electrochemical workstation

Fig. 2 TGA curves of the Ni-Co precursor in air atmosphere.

(Zahner-Zennium) in the frequency range of 100 kHz to 10 mHz with an amplitude of 5 mV.

### 3. Results and discussion

#### 3.1 Material characterization

Fig. 2 shows the thermogravimetric (TGA) curve of the assynthesized Ni–Co–O precursor, measured from 30 to 800 °C at a heating rate of 3 °C min<sup>-1</sup> in air atmosphere. The initial 1.1% weight loss at the low temperature (30–250 °C) would result from the loss of the evaporation of moisture and the decomposition of crystal water in the precursor. The following 20.4% weight loss with a big step occurs between 250 and 450 °C, which might be attributed to the conversion of anhydrous precursors to spinel cubic crystals. Therefore, we reasonably chose 450 °C as calcination temperature in our experiment.

The morphology and microstructure of the as-prepared NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> powders are characterized by scanning electron microscopy as shown in Fig. 1. It is clear that NiCo<sub>2</sub>O<sub>4</sub> powders are all rose flower-like morphology (Fig. 3(a)), which is composed of thin transparent nanosheets with a thickness of ~20 nm. Fig. 3(b) reveals that the nanosheets of NiCo<sub>2</sub>O<sub>4</sub> contains many micro-pores, which is mainly attributed to the organics loss accompanying removal of PVP and gases during the calcination process.<sup>22,23</sup> Such hierarchical structure would be

Fig. 3 SEM images of the as-prepared NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders.

Paper

Fig. 4 (a) Nitrogen sorption isotherms and (b) pore diameter distribution of  $NiCo_2O_4$  and  $NiCo_2O_4$ @TiO<sub>2</sub> powders.

highly desirable for rapid Li-ion diffusion and electron transfer. Porosity structure of the NiCo<sub>2</sub>O<sub>4</sub> nanosheet may be benefit for lithium-ion transportation from the electrolyte into the active sites with less resistance, and buffer efficiently large volume expansion during the Li-ion insertion/extraction processes.<sup>24</sup> With TiO<sub>2</sub>-coating, NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders also maintain the nanosheet-built flower-like nanostructure as same to the bare one, shown in Fig. 3(c). In contrast, the nanosheets of NiCo<sub>2</sub>-O<sub>4</sub>@TiO<sub>2</sub> have a smooth and integrated surface morphology and the micro-pores on the "petals" disappears, indicating TiO<sub>2</sub> layer is uniformly coated on the nanosheet surface.

Fig. 4(a) presents nitrogen adsorption-desorption isotherms of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> powders, indicating a typical hysteresis mesoporous system.12,25 According to Brunauer-Emmett-Teller (BET) equation, the specific surface areas of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> are calculated to be 98.78 and 78.09  $m^2 g^{-1}$ , respectively. Fig. 4(b) shows the corresponding pore-size distribution based on Barrett-Joyner-Halenda (BJH) method, indicating that NiCo2O4@TiO2 have larger average pore size (10.3 nm) that (5.6 nm) of NiCo<sub>2</sub>O<sub>4</sub>. An increase in average pore size and reduction in surface area could be reasonably explained by the disappearance of micro-pores (5.6 nm) because of TiO<sub>2</sub>-coating. The obtained results are consistent with the analysis from SEM images. The distribution of corresponding elements of NiCo2O4@TiO2 is investigated by EDS. Element mapping images for Ni, Co and Ti in NiCo<sub>2</sub>- $O_4$  (TiO<sub>2</sub> powders (Fig. 5) reveal that the corresponding elements uniformly distribute on the surface of the NiCo<sub>2</sub>-O<sub>4</sub>(a)TiO<sub>2</sub> particles.

Fig. 6(a) shows the XRD patterns of  $NiCo_2O_4$  and  $NiCo_2-O_4$  and  $NiCo_4-O_4$  and NiC

Fig. 5 Element mapping images of NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders.

of a spinel NiCo<sub>2</sub>O<sub>4</sub> structure with space group Fd3m (JCPDS card no. 73–1702).<sup>22,26</sup> It is found that no visible differences in XRD patterns between two composites, which is attributed to the low content of TiO<sub>2</sub> phase. Fig. 6(b) presents Raman spectra of the as-prepared NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> samples. Five obvious peaks at 212, 313, 366, 536 and 671 cm<sup>-1</sup> are found in the Raman spectrum of NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> composites, which can be assigned to the vibrational modes of spinel NiCo<sub>2</sub>O<sub>4</sub>.<sup>27,28</sup> The peak at around 149 cm<sup>-1</sup> is related to the E<sub>g</sub> vibration modes of the TiO<sub>2</sub> anatase structure.<sup>29</sup> The TiO<sub>2</sub> content in NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> composite is further determined to be *ca.* 3.53 wt% by inductively coupled plasma OES spectrometer (ICP).

The elemental composition and the oxidation state of the  $NiCo_2O_4(@TiO_2 \text{ powder} \text{ is further characterized by X-ray photoelectron spectroscopy (XPS) measurements and the corresponding results are present in Fig. 7(a–e). The survey spectrum (Fig. 7(a)) reveals the presence of Ni, Co, Ti and O as well as C elements without any other impurities. By using a Gaussian fitting method, the Ni 2p core-level spectrum (Fig. 7(b)) has two spin–orbit doublets and two shake-up satellites, which are in good agreement with the characteristic of Ni<sup>2+</sup> and Ni<sup>3+</sup>.<sup>30</sup> Similarly, two spin–orbit doublets and shake-up satellites can$ 

Fig. 6 (a) XRD patterns of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders; (b) Raman spectra of the as-prepared NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders.

also be observed in the Co 2p spectrum, corresponding to the characteristic of  $\text{Co}^{2+}$  and  $\text{Co}^{3+}$ .<sup>30</sup> The peaks located at 458.7 and 464.4 eV are attributed to the Ti  $2p_{3/2}$  and Ti  $2p_{1/2}$  spin–orbit doublets, indicating the predominant state of the Ti element in composite is Ti<sup>4+</sup>.<sup>31</sup> The O 1s spectra can be divided into two main oxygen peaks at 529.6 and 531 eV. The peak located at 529.6 eV is typical characteristic of metal–oxygen bonds.<sup>32</sup> The XPS results are in good agreement with the analysis from XRD and ED measurements.

Fig. 8(a) shows the rate capabilities of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>-O4@TiO2 electrodes at various current density, measured from 100 to 2000 mA  $g^{-1}$  in rising order and subsequently followed by returning 1000, 500 and 200 mA g<sup>-1</sup>. In comparison, NiCo<sub>2</sub>-O<sub>4</sub>(a)TiO<sub>2</sub> composite exhibits better rate performance than that of the bare one, especially at a higher rate. When the current density increases to 100, 200, 500, 1000 and 2000 mA  $g^{-1}$ , the  $NiCo_2O_4$  (a) TiO\_2 electrode shows reversible discharge capacities of 988, 930, 840, 750 and 624 mA h  $g^{-1}$ , respectively. Even at a high current density of 2000 mA  $g^{-1}$ , the discharge capacity still retains 63.2%. When the current density returns back to 1000, 500 and 200 mA  $g^{-1}$ , the NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrode still recovers 735, 837 and 1004 mA h g<sup>-1</sup>, indicating excellent structure stability of the nano-composite. In contrast, the NiCo<sub>2</sub>O<sub>4</sub> electrode delivers a lower discharge capacity at current density. The discharge capacities of the NiCo<sub>2</sub>O<sub>4</sub> electrode are measured to be 983, 878, 778, 683 and 562 mA  $g^{-1}$  at the same respective current density. It has been reported that small anatase TiO<sub>2</sub> particles would be turning from an insulator into an electronic conductor during the Li<sup>+</sup> insertion possess.<sup>33,34</sup> Therefore, TiO<sub>2</sub>-coating on NiCo<sub>2</sub>O<sub>4</sub> nanosheets is beneficial for both structural stability as well as the rate capability.

Fig. 8(b) presents the cycling performance of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> electrodes at a current density of 100 mA  $g^{-1}$ . In comparison with NiCo2O4, the capacity loss is significantly suppressed after coating with TiO<sub>2</sub>. The initial discharge capacity at 100 mA g<sup>-1</sup> of NiCo<sub>2</sub>O<sub>4</sub> is 1424 mA h g<sup>-1</sup> and found to decrease to 815 mA h  $g^{-1}$  after 60 cycles (*i.e.*, only 57% of its initial discharge capacity). The discharge capacity of the NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> is found to decay gradually with continuous cycling, retaining 78% of its maximum discharge capacity after 60 cycles. In addition, the coulombic efficiency of NiCo<sub>2</sub>O<sub>4</sub> is relatively low and unstable, which might result from the SEI formation repeatedly on NiCo2O4 nanosheet during the charge/ discharge processes.<sup>19</sup> Similar results are reported in Lotfabad's work.33 Here, we have made a comparison of the electrochemical performances between our NiCo2O4(a)TiO2 and other NiCo2O4 with different morphologies previously reported, as summarized in Table 1. It is found that NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> nanocomposites exhibit superior cycling stability, indicating its potential application in high-energy lithium-ion batteries.

Fig. 9(a and b) shows cyclic voltammetry profiles of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> electrode for the first six cycles at a scan rate of 0.1 mV s<sup>-1</sup> and from 0.01 to 2.5 V. Two peaks are observed at around 0.6 and 0.9 V in the initial cathodic sweep for both samples, which are assigned to the formation of the solid electrolyte interface layer and the reaction of Co<sup>3+</sup> and Ni<sup>2+</sup> to Co<sup>0</sup> and Ni<sup>0</sup>, respectively.<sup>41</sup> Two oxidation peaks at around 1.4

Fig. 7 XPS spectra of (a) survey spectrum, (b) Ni 2p, (c) Co 2p, (d) Ti 2p and (e) O 1s for the NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> product.

and 2.2 V are also observed in the initial anodic sweep, which are attributed to the oxidation of Co<sup>0</sup> and Ni<sup>0</sup> to Co<sup>3+</sup> and Ni<sup>2+</sup>, respectively.<sup>42</sup> According to the previous reports,<sup>43</sup> the redox reactions can be expressed as follows:

$$Co + Li_2O \leftrightarrow CoO + 2Li^+ + 2e^-$$

$$CoO + 1/3Li_2O \leftrightarrow 1/3Co_3O_4 + 2/3Li^+ + 2/3e^-$$
 (4)

 $NiCo_2O_4 + 8Li^+ + 8e^- \rightarrow Ni + 2Co + 4Li_2O$ (1)

$$Ni + Li_2O \leftrightarrow NiO + 2Li^+ + 2e^-$$
(2)

In comparison with  $NiCo_2O_4$ , the CV curves from 2nd to 6th cycles for  $NiCo_2O_4$  (a)TiO<sub>2</sub> exhibit a better overlapping degree, indicating a better reversibility of the electrochemical reactions.

(3)

To further investigate the potential mechanism behind the improved performances with surface-modified of  $TiO_2$  layer, the cells after cycling are disassembled, washed, dried in vacuum and characterized by SEM. Fig. 10 presents the morphologies of  $NiCo_2O_4$  and  $NiCo_2O_4$ @TiO\_2 powders characterized by SEM after 10 and 30 cycles, respectively. It is obvious that  $NiCo_2O_4$  powders has serious structure-deterioration (pulverization or

Fig. 9 Cyclic voltammetry profiles of NiCo\_2O\_4 and NiCo\_2O\_4@TiO\_2 electrodes.

aggregation) and losses its flower-like structure with increasing cycles due to the repeated volume change between metals and metal oxides. The aggregation of the active materials tends to reduce the effective contact areas between active materials and the electrolyte. In contrast, NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders can remain in the flower-like structure well, which further confirms that TiO<sub>2</sub>-layer would stabilize structure of the active materials and consequently offer more active sites during the lithium-ion insertion/extraction process. Combined with the analysis of the SEM images after cycling, it is expected that stable hierarchical nanostructures are desirable for the improved electrochemical performances.

Electrochemical impedance spectra are carried out to get insight into the improved rate and cyclic performances of NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub>. Fig. 11(a) presents the typical EIS of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrode in the fully discharged state. Both EIS profiles consist of two depressed semicircles in the medium-to-high frequency range and a straight line in the lowfrequency region. According to the equivalent circuit in the inset of Fig. 11(a), the charge-transfer resistance ( $R_{ct}$ ) are

Fig. 10 SEM images of the NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders after 10 and 30 cycles, respectively.

calculated as 36.6  $\Omega$  for NiCo<sub>2</sub>O<sub>4</sub> and 20.4  $\Omega$  for NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub>, respectively. The decrease in  $R_{\rm ct}$  for NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> would derive from the more stable structure by TiO<sub>2</sub>-coating with continuous cycling.<sup>44</sup> The TiO<sub>2</sub>-coating layer is expected to efficiently prevent the pulverization of NiCo<sub>2</sub>O<sub>4</sub> during the Li<sup>+</sup> intercalation/extraction process and mediate the increase in charge transfer resistance of the composites, which facilitates Li-ions transfer at the interface between the active material and electrolyte. As a result, the electrochemical performances are improved.

The diffusion coefficients  $(D_{\rm Li})$  of the Li-ion kinetic of the cells can be also calculated according to the EIS profiles in the low frequency.

$$\sigma = \frac{RT}{n^2 F^2 A \sqrt{2}} \left( \frac{1}{C_{\rm Li} D_{\rm Li}^{1/2}} \right) \tag{5}$$

$$Z_{\rm re} = R + \sigma \omega^{-1/2} \tag{6}$$

*R*, *T* and *F* are the mass gas constant, absolute temperature and Faraday's constant; *A*, *n* and *C*<sub>Li</sub> are the surface area of the electrode, the number of electrons per molecule during oxidation and the molar volume of active material;  $\sigma$ , *Z*<sub>re</sub> and  $\omega$  are the Warburg factor, the real part of the impedance and the frequency. Based on the slope coefficient of *Z*<sub>re</sub> to  $\omega^{-1/2}$  (see Fig. 11(b)), the corresponding lithium diffusion coefficients *D*<sub>Li</sub> of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders are calculated as  $2.57 \times 10^{-12}$  cm<sup>2</sup> s<sup>-1</sup> and  $8.18 \times 10^{-12}$  cm<sup>2</sup> s<sup>-1</sup> respectively, suggesting the rapid diffusion of lithium-ions of NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrode.

To evaluate the effect of TiO<sub>2</sub>-coating on the Li-ion diffusion during the charge/discharge process, the impedance spectra under different discharge states for NiCo2O4 and  $NiCo_2O_4$  (a) TiO\_2 electrodes are continuously measured, shown in Fig. 12(a and b). According to eqn (5) and (6), the corresponding Li<sup>+</sup>-ion diffusion coefficients of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrodes are calculated. Fig. 12(c) presents lithium-ion diffusion behaviors during the lithium-ion insertion process. Both electrodes demonstrate similar lithium-ion diffusion behavior. On the whole, NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrode exhibits larger Li<sup>+</sup> diffusion coefficients than those of the bare one, indicating that TiO<sub>2</sub>-coating does readily facilitate the Li<sup>+</sup> diffusion in composites. It is worth noting that NiCo2O4@TiO2 electrode has much larger diffusion coefficients of lithium-ions in the voltage range from 1.0 to 0.01 V, which might be attributed to the lithium ion insertion in TiO2. It is expected that lithiuminserted Li<sub>x</sub>TiO<sub>2</sub> anatase would turn from an insulator into an electronic conductor during the Li<sup>+</sup> insertion possess, resulting in enhanced electron-transfer in composites.<sup>33</sup> As a result, TiO<sub>2</sub> coating on NiCo<sub>2</sub>O<sub>4</sub> is potentially beneficial for the improved rate capability as well as the structural integrity of the composite.

Kelvin probe atomic force microscopy is used to study the influence of TiO<sub>2</sub>-coating on the Li-ion kinetic behavior in composites. Fig. 13(a and b) shows the surface potential maps over a scan area of 200 nm  $\times$  200 nm of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>-O<sub>4</sub>@TiO<sub>2</sub> powders before cycling. Fig. 13(c) presents the surface potential image of Au foil acting as reference sample. According to our prior work,<sup>45</sup> the work functions of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>-O<sub>4</sub>@TiO<sub>2</sub> powders are calculated based on the surface potential

**Fig. 11** (a) Typical EIS of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrode in the fully discharged state and the equivalent circuit for EIS fitting; (b) real parts of the complex impedance  $Z_{\rm re}$  vs.  $\omega^{-1/2}$  for NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrodes.

profiles and the corresponding results are shown in Fig. 13(d). Here, the work functions of the SFM-tip ( $\phi_{tip}$ ) is calibrated by Au foil, whose work function ( $\phi_{Au}$ ) is 5.31 eV. It is found that NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> has a smaller work function (~5.41 eV) than that (~5.51 eV) of the NiCo<sub>2</sub>O<sub>4</sub>. The measured work function of NiCo<sub>2</sub>O<sub>4</sub> is close to the reported value (5.53 eV).<sup>46,47</sup> The larger work function suggests the more energy required for electrons to escape from the composites. As a result, the electrochemical performances of the composites are enhanced with surface-modified with TiO<sub>2</sub>-coating. These obtained results are consist with the analysis of EIS measurements.

The reduced work function of NiCo<sub>2</sub>O<sub>4</sub>(a)TiO<sub>2</sub> could be explained phenomenologically based on the energy-band model. As shown in Fig. 14(a), electrons transfer occurs from TiO<sub>2</sub> to NiCo<sub>2</sub>O<sub>4</sub> until the Fermi levels are aligned due to the smaller work function (~4.5 eV) of anatase TiO<sub>2</sub>.<sup>48</sup> As a result, the TiO<sub>2</sub> is positively charged and the NiCo<sub>2</sub>O<sub>4</sub> is negatively charged near its surface due to electrostatic induction because of electrostatic induction. Meanwhile, a corresponding electric field (*E*) is built up between them, shown in Fig. 14(b). Such

Fig. 12 (a, b) The impedance spectra and (c) corresponding Li-ion of diffusion coefficients of  $NiCo_2O_4$  and  $NiCo_2O_4$ @TiO<sub>2</sub> electrodes under different discharge states.

electric field could facilitate Li-ion diffusion from positivelycharged  $TiO_2$  to negatively-charged  $NiCo_2O_4$ , and electron transfer from  $NiCo_2O_4$  to  $TiO_2$  across heterojunction interfaces. With the help of the electric field, more electrons in  $NiCo_2O_4$ matrix would transfer through  $TiO_2$  rather than  $NiCo_2O_4/NiCo_2O_4$  interface during the lithium insertion process. Moreover,  $TiO_2$  coated on  $NiCo_2O_4$  could effectively suppress the pulverization of  $NiCo_2O_4$  matrix due to the volume change in

Fig. 13 (a, b) Surface potential maps over a scan area of 200 nm  $\times$  200 nm of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> powders before cycling; (c) surface potential image of Au foil acting as reference sample; (d) work functions of NiCo<sub>2</sub>O<sub>4</sub> and NiCo<sub>2</sub>O<sub>4</sub>@TiO<sub>2</sub> electrodes.

Fig. 14 (a) The energy-level model for explaining the improved electron transfer in  $NiCo_2O_4@TiO_2$  electrodes; (b) a built electric field (*E*) between  $NiCo_2O_4$  and  $TiO_2$ .

the charge/discharge process. As a result, the electrochemical performances are enhanced.
