# Impact of ambient gases on the mechanism of [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>]-promoted nerve-agent decomposition†‡

Alexey L. Kaledin,<sup>a</sup> Darren M. Driscoll,<sup>b</sup> Diego Troya,<sup>b</sup> Daniel L. Collins-Wildman,<sup>c</sup> Craig L. Hill,<sup>b</sup> John R. Morris<sup>\*b</sup> and Djamaladdin G. Musaev<sup>†ab</sup>

The impact of ambient gas molecules (X), NO<sub>2</sub>, CO<sub>2</sub> and SO<sub>2</sub> on the structure, stability and decontamination activity of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> polyoxometalate was studied computationally and experimentally. It was found that Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> absorbs these molecules more strongly than it adsorbs water and Sarin (GB) and that these interactions hinder nerve agent decontamination. The impacts of diamagnetic CO<sub>2</sub> and SO<sub>2</sub> molecules on polyoxoniobate Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> were fundamentally different from that of NO<sub>2</sub> radical. At ambient temperatures, weak coordination of the first NO<sub>2</sub> radical to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> conferred partial radical character on the polyoxoniobate and promoted stronger coordination of the second NO<sub>2</sub> adsorbent to form a stable diamagnetic Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/(NO<sub>2</sub>)<sub>2</sub> species. Moreover, at low temperatures, NO<sub>2</sub> radicals formed stable dinitrogen tetroxide (N<sub>2</sub>O<sub>4</sub>) that weakly interacted with Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>. It was found that both in the absence and presence of ambient gas molecules, GB decontamination by the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> species proceeds *via* general base hydrolysis involving: (a) the adsorption of water and the nerve agent on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/(X), (b) concerted hydrolysis of a water molecule on a basic oxygen atom of the polyoxoniobate and nucleophilic addition of the nascent OH group to the phosphorus center of Sarin, and (c) rapid reorganization of the formed pentacoordinated-phosphorus intermediate, followed by dissociation of either HF or isopropanol and formation of POM-bound isopropyl methyl phosphonic acid (i-MPA) or methyl phosphonofluoridic acid (MPFA), respectively. The presence of the ambient gas molecules increases the energy of the intermediate stationary points relative to the asymptote of the reactants and slightly increases the hydrolysis barrier. These changes closely correlate with the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-X complexation energy. The most energetically stable intermediates of the GB hydrolysis and decontamination reaction were found to be Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA-(i-POH) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA)-HF both in the absence and presence of ambient gas molecules. The high stability of these intermediates is due to, in part, the strong hydrogen bonding between the adsorbates and the protonated [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X/H]<sup>+</sup>-core. Desorption of HF or/and (i-POH) and regeneration of the catalyst required deprotonation of the [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X/H]<sup>+</sup>-core and protonation of the phosphonic acids i-MPA and MPFA. This catalyst regeneration is shown to be a highly endothermic process, which is the rate-limiting step of the GB hydrolysis and decontamination reaction both in the absence and presence of ambient gas molecules.

## Introduction

The design of materials that can rapidly, fully, and catalytically decontaminate chemical warfare agents (CWAs) and other toxic compounds is an increasingly active area of research and one that presents some questions in fundamental chemistry.<sup>1–5</sup> As suggested by enzymatic chemistry, some of the most effective strategies for CWA destruction involve catalyzed hydrolysis reactions.<sup>4</sup> Specifically, it is well established that the P–X bonds (X = F, CN, SR, *etc.*) of organophosphorus (OP) nerve agents rapidly inactivate acetylcholinesterase (a serine hydrolase), the enzyme that facilitates hydrolysis of the neurotransmitter acetylcholine in the nervous system. This inactivation occurs through rapid nucleophilic addition and irreversible binding of

the serine OH to the phosphorus atom of the nerve agent. Thus, an atomistic/molecular level understanding of the hydrolysis of OP compounds by nucleophilic addition and other processes may lead to the development of more effective materials and catalysts for nerve agent decontamination. Ongoing research efforts have identified several organic and inorganic materials, including metal–organic frameworks (MOFs, especially UiO-66, NU-1000 and MOF-808),<sup>5–10</sup> polyoxometalates (POMs),<sup>11–14</sup> MOF/POM hybrid materials,<sup>15,16</sup> zirconium hydroxide,<sup>17</sup> zeolites,<sup>18</sup> and organic polymers,<sup>19</sup> as effective OP hydrolysis materials.

Recently, the use of POMs to catalyze nerve agent decontamination has attracted wide attention, in part because POMs are molecular representations of metal oxides and are thus far more amenable than the latter to extensive synthetic compositional alteration and characterization at the molecular level.<sup>20,21</sup> Polyoxoniobates (PONbs), including  $[\text{Nb}_6\text{O}_{19}]^{8-}$ , are effective OP nerve agent hydrolysis compounds because their high negative charge densities (negative charge per polyanion oxygen) render them highly basic and nucleophilic. Thus, it is not surprising that the synthesis and in-depth analysis of the structures and reactivities of various (alkali and organic) salts of PONbs continue to be the focus of extensive studies.<sup>22,23</sup> These studies show that the structures and, consequently, the catalytic activities of these materials for nerve agent decontamination depend on many factors, including (but not limited to) the nature of the counter-cation, the pH of the solution, the aggregate state (powder or solid-state material) of the catalyst, the real-time environmental conditions, and the nature and concentration of ambient gas molecules.

Earlier research on Lindqvist hexaniobate alkali salts ( $\text{M}_8\text{Nb}_6\text{O}_{19}$ ,  $\text{M} = \text{Li}, \text{K}, \text{Cs}$ ) reported rapid hydrolysis of the OP agent Sarin (GB, propan-2-yl methylphosphonofluoridate, see Scheme 1) both in aqueous solution and at the gas–surface interface.<sup>11</sup> Small-angle X-ray scattering (SAXS) measurements showed aggregation of the OP compounds on the polyoxoniobate (PONb), which led to the suggestion that the reaction follows a general base hydrolysis mechanism.<sup>12</sup> Our subsequent computational study on the mechanism of decomposition of GB by a Cs-salt of PONb,  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  (or  $\text{CsPONb}$ ), confirmed the general base hydrolysis mechanism of this reaction at the gas–surface interface.<sup>24</sup>

Briefly, we have found that GB degradation by  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  includes the following elementary steps (see Scheme 1): (a) the adsorption of water and the nerve agent on the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  species, (b) concerted dissociation of the adsorbed water molecule on a basic oxygen atom of the polyoxoniobate and nucleophilic addition of the nascent OH group to the phosphorus center of the nerve agent, (c) rapid reorganization of the resulting pentacoordinated phosphorus intermediate by dissociation of either HF or isopropanol, and formation of POM-bound isopropyl methyl phosphonic acid (i-MPA) or methyl phosphonofluoridic acid (MPFA), respectively. The calculations showed that the phosphonic acids i-MPA and MPFA are strongly bound to the protonated  $[\text{Cs}_8\text{Nb}_6\text{O}_{19}\text{H}]^+$ -core through hydrogen bonds and electrostatic interactions with the Cs counter-ions, suggesting that full catalyst regeneration may require additional treatment and depends on the nature of the counter-cations as well as the real-time (ambient) experimental conditions.

Although PONb catalysts have been shown to react with CWAs, the chemistry has yet to be characterized in the presence of ambient gases (for example,  $\text{NO}_2$ ,  $\text{CO}_2$  and  $\text{SO}_2$ ), which may affect the stabilities, structural motifs, and activities of the PONb catalysts. Because this issue is vital to the application of PONbs as decontamination catalysts in real conditions, this paper probes the impact of the common battlefield contaminants  $\text{NO}_2$ ,  $\text{CO}_2$  and  $\text{SO}_2$  on the structure, stability and decontamination activity of the exemplary PONb species  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ . This study addresses in depth the effects of these ambient gases on the structures of the catalysts and the base hydrolysis mechanism for Sarin degradation using density functional theory (DFT) calculations and infrared (IR) spectroscopy.

## Results and discussion

### A. Structure of $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ in the presence of gaseous $\text{CO}_2$ , $\text{NO}_2$ and $\text{SO}_2$

Here, we divide our discussion into two subsections. First, we discuss the interaction of diamagnetic  $\text{CO}_2$  and  $\text{SO}_2$  molecules with  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ ; then, we present our findings on the interactions between  $\text{NO}_2$  radical and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ .

**A1. Structure of  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  in the presence of gaseous  $\text{CO}_2$  and  $\text{SO}_2$ .** Our calculations reveal that  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  very strongly binds the ambient gas molecules  $\text{CO}_2$  and  $\text{SO}_2$  at various (terminal  $\text{O}^t$  and/or bridging  $\text{O}^b$ ) sites to form  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$  adducts. As reported in Table 1, where we present the calculated adsorption energies, there is a clear preference of adsorption of both  $\text{CO}_2$  and  $\text{SO}_2$  at the terminal oxygen site rather than at the bridging oxygen site. Indeed, the calculated enthalpies and free energies of adsorption (presented as  $\Delta H/\Delta G$ ) of  $\text{Cs}_8\text{Nb}_6\text{O}_{19} + \text{X} \rightarrow \text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$  upon coordination of X to the  $\text{O}^t$  and  $\text{O}^b$  sites are  $-29.0/-23.2$  and  $-16.7/-10.8$  kcal mol<sup>-1</sup> for  $\text{X} = \text{CO}_2$  and  $-47.6/-40.3$  and  $-34.1/-26.6$  kcal mol<sup>-1</sup> for  $\text{X} = \text{SO}_2$ , respectively.

The factors that impact the strength of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$  bonding and site-preference of absorption were analyzed by investigating the resulting geometries of these complexes. From Fig. 1, where we present the most important geometries of the

Scheme 1 Schematics of: (a) the mechanism of Sarin (GB) hydrolysis (reported in ref. 24) promoted by the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  polyoxoniobate and (b) the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  polyoxoniobate.

**Table 1** Adsorption energies (total electronic  $E$ , enthalpy  $H$  and Gibbs free energy  $G$  in kcal mol<sup>-1</sup>) defined as energy differences of the complex Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/ $X$  and its two separated fragments, Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> +  $X$ , where  $X$  = CO<sub>2</sub>, NO<sub>2</sub> and SO<sub>2</sub>, as shown in the leftmost column. The superscripts "t" and "μ" indicate the position where the molecule is adsorbed on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>; Cs<sup>N</sup> indicates NO<sub>2</sub> adsorption to two Cs counter-cations in a symmetric manner

Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/ $X$ (O<sup>t</sup>) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/ $X$ (O<sup>μ</sup>) isomeric species for  $X$  = CO<sub>2</sub> and SO<sub>2</sub> (for full geometries of these species, see the ESI†), we make the following conclusions:

(a) The CO<sub>2</sub> molecule in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>t</sup>) is bound to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> *via* multiple interactions, including two (C=O)<sub>CO<sub>2</sub></sub>...Cs interactions and one C-O<sup>t</sup> interaction. The long calculated bond distances for the Cs-O<sup>1</sup>, Cs-O<sup>2</sup> and Cs-C interactions (3.23, 3.25 and 3.28 Å, respectively) indicate they are relatively weak. In contrast, the C-O<sup>t</sup> interaction is stronger, with a bond distance of 1.39 Å. As a result of this strong interaction, the Nb-O<sup>t</sup> distance is elongated from 1.80 Å to 2.02 Å (see Fig. 1). Thus, while the interactions with the Cs cations provide additional stability to the complex Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>t</sup>), the primary

interaction occurs between the C atom of CO<sub>2</sub> and the terminal oxygen atom of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>.

In the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>μ</sup>) isomer, where CO<sub>2</sub> interacts with a bridging oxygen, the C-O<sup>μ</sup> bond distance is longer (calculated to be 1.44 Å) than the C-O<sup>t</sup> bond distance in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>t</sup>), while the Cs-O<sup>1</sup> and Cs-O<sup>2</sup> interactions are slightly stronger (based on the calculated Cs-O<sup>1</sup> and Cs-O<sup>2</sup> distances). The above presented geometry parameters of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>t</sup>) and Cs<sub>8</sub>PONb/CO<sub>2</sub>(O<sup>μ</sup>) not only explain the calculated energy difference between these species, but are also consistent with the amounts of charge transfer from Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> to CO<sub>2</sub>: in the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>t</sup>) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>μ</sup>) complexes, almost 0.8 | $e$ | and 0.4 | $e$ | negative charge is transferred from Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> to CO<sub>2</sub>, respectively. Furthermore, the putative CO<sub>3</sub>-group in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>t</sup>) has a total negative charge of 1.52 | $e$ |.

The strong coordination of CO<sub>2</sub> to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> is also supported by IR spectroscopic studies, where the adsorption of CO<sub>2</sub> onto Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> was investigated by recording the infrared spectra before, during, and after exposure of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> to a constant flux of CO<sub>2</sub>. Upon adsorption of CO<sub>2</sub> on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>, three prominent features appeared in the infrared spectrum (Fig. 2, i) at 1659 cm<sup>-1</sup>, 1290 cm<sup>-1</sup> and 1229 cm<sup>-1</sup>. Interestingly, we observed no feature in the infrared spectrum around 2300 cm<sup>-1</sup>, which would be associated with a linear CO<sub>2</sub> molecule bound to the POM surface. The 1229 cm<sup>-1</sup> and 1290 cm<sup>-1</sup> bands are consistent with the IR-inactive symmetric stretch from the gas-phase ( $\nu_1$ (C-O)), which becomes IR active upon binding to the POM. The 1659 cm<sup>-1</sup> band is likely related to the antisymmetric  $\nu_3$ (C-O) stretch of CO<sub>2</sub>/CO<sub>3</sub> (occurs at 2349 cm<sup>-1</sup> in the gas-phase<sup>25</sup> and significantly redshifts upon adsorption). The presence of both the  $\nu_1$  and  $\nu_3$  bands in the infrared spectrum indicates a bent structure of the adsorbate at the surface. Upon evacuation of CO<sub>2</sub> from the chamber, the 1229 cm<sup>-1</sup> spectroscopic feature diminishes, indicating that this band corresponds to the vibrational motion of weakly bound CO<sub>2</sub> species on the surface (Fig. 2, ii); however, the two other features (1659 and 1290 cm<sup>-1</sup>) persist until annealing the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> sample at 423 K (Fig. 2, iii). The elevated

**Fig. 1** Adsorption of the ambient gas molecules CO<sub>2</sub> and SO<sub>2</sub> on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> at the O<sup>t</sup> sites (left) and bridging sites (right) with their important geometry parameters (in Å).

**Fig. 2** Infrared spectra recorded during and after the adsorption of CO<sub>2</sub> onto Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> at 300 K. (i) Adsorption of 100 mTorr of CO<sub>2</sub>. (ii) After CO<sub>2</sub> evacuation. (iii) After CO<sub>2</sub> evacuation and thermal treatment at 423 K.

temperature required to fully remove the CO<sub>2</sub> suggests that the molecules responsible for these infrared bands are strongly bound to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>. The experimentally observed IR features are in full agreement with the DFT calculations (harmonic, unscaled). Indeed, the two prominent IR active features at 1290 and 1659 cm<sup>-1</sup>, which are ascribed to the bending and asymmetric CO stretch motions of a bent CO<sub>2</sub> molecule, are calculated to be 1316 and 1317 cm<sup>-1</sup> (for the bend) and 1702 and 1719 cm<sup>-1</sup> (for the asymmetric stretch) in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>l</sup>) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>(O<sup>h</sup>), respectively. Thus, the above presented experimental and computational analysis shows that a large fraction of the adsorbed CO<sub>2</sub> strongly binds to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>. Once at the surface, the molecule adopts a bent geometry, which activates the ν<sub>1</sub> vibrational motion toward absorption of infrared radiation.

(b) The geometric features of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/SO<sub>2</sub>(O<sup>l</sup>) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/SO<sub>2</sub>(O<sup>h</sup>) adducts are similar to those of their CO<sub>2</sub> analogs: among the interactions, the strongest are the S–O<sup>l</sup> and S–O<sup>h</sup> interactions, with 1.70 and 1.79 Å bond distances, respectively. These geometry parameters are consistent with the greater stability of the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/SO<sub>2</sub>(O<sup>l</sup>) isomer. Furthermore, comparison of the calculated Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>–X binding energies shows that SO<sub>2</sub> interacts with Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> much more strongly, by nearly a factor of two, than CO<sub>2</sub>. However, both molecules clearly persist on the POM at ambient and well above ambient temperatures.

Further calculations showed that single Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> species can bind several CO<sub>2</sub> and SO<sub>2</sub> molecules. As seen in Table 2, where we have summarized the adsorption energies as a function of the number of molecules adsorbed at the six O<sup>l</sup> sites, there is a pronounced monotonic convergence of the electronic and enthalpy binding energies up to n = 6. The free energies, on the other hand, reveal thermodynamic instability for CO<sub>2</sub> adsorption at larger values of n, suggesting that only the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/(CO<sub>2</sub>)<sub>n</sub> species with n ≤ 4 are viable. The Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/(SO<sub>2</sub>)<sub>n</sub> species may still be stable for n > 6.

## A2. Structure of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> in the presence of NO<sub>2</sub> radicals.

As one might expect, the interaction of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> with NO<sub>2</sub> radicals is conceptually different than those discussed above for the diamagnetic CO<sub>2</sub> and SO<sub>2</sub> molecules. Indeed, at first, in the

**Table 2** Adsorption of n(X) (X = CO<sub>2</sub> and SO<sub>2</sub> and n = 1 to 6) on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> at its O<sup>l</sup>-sites, reported as incremental ΔZ<sub>n,n-1</sub>(Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X) = Z<sub>n</sub>(Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X) – Z<sub>n-1</sub>(Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X) – Z(X) energies (where Z = E, H or G) (in kcal mol<sup>-1</sup>)

n	X = CO <sub>2</sub>			X = SO <sub>2</sub>		
	Z = E	Z = H	Z = G	Z = E	Z = H	Z = G
1	-29.1	-29.0	-23.2	-48.2	-47.6	-40.3
2	-22.9	-21.8	-11.2	-43.3	-42.4	-27.6
3	-19.6	-18.9	-9.6	-38.8	-37.1	-27.3
4	-13.3	-12.5	-0.7	-34.2	-32.9	-19.8
5	-7.3	-6.6	4.4	-26.9	-25.9	-14.9
6	-2.2	-2.0	6.9	-29.0	-27.9	-16.9

gas-phase and at low temperatures, NO<sub>2</sub> radicals are in equilibrium with dinitrogen tetroxide, N<sub>2</sub>O<sub>4</sub>, while higher temperatures shift the equilibrium towards nitrogen dioxide.<sup>26</sup>

The calculations show that N<sub>2</sub>O<sub>4</sub> is planar, with an N–N bond distance of 1.85 Å, which is significantly longer than the average N–N single bond length of 1.45 Å; this species has a dimerization energy of ΔE/ΔH/ΔG = 19.8/17.3/5.6 kcal mol<sup>-1</sup>. Unlike NO<sub>2</sub>, N<sub>2</sub>O<sub>4</sub> is diamagnetic and coordinates to the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> catalyst (see Fig. 3) with a Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>–N<sub>2</sub>O<sub>4</sub> interaction energy of ΔE/ΔH/ΔG = -25.3/-25.3/-18.5 kcal mol<sup>-1</sup>. Secondly, as shown in Table 1 and Fig. 3, the “free” NO<sub>2</sub> radical (at ambient temperature) can interact with polyoxoniobate to form the [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>]/NO<sub>2</sub> adduct. This adduct exists in two energetically stable isomeric forms, Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(O<sup>l</sup>) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(Cs<sup>N</sup>); the most favorable form is Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(Cs<sup>N</sup>), where the N atom of NO<sub>2</sub> interacts with two Cs centers (with Cs<sup>1</sup>–N and Cs<sup>2</sup>–N distances of 3.42 and 3.44 Å). To our surprise, these Cs–N interactions lead to electron transfer from Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> to NO<sub>2</sub> in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(Cs<sup>N</sup>), as evidenced by population analysis: the calculated Mulliken spin/charge is NO<sub>2</sub>(Cs<sup>N</sup>) = 0.34/-0.65 |e|. Thus, as a result of these interactions, almost 0.65 |e| charge is transferred from Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> to NO<sub>2</sub>; and, consequently, the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> unit develops partial radical character. Further analysis shows that most of the unpaired spin of Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> is located on the internal O<sup>IN</sup>-center (~0.24 |e|) and the bridging O<sup>h</sup> (~0.14 |e|) located close to the Cs atoms coordinated to NO<sub>2</sub>, while the remaining spin is delocalized on all other atoms of the polyoxoniobate. Similarly, but to a lesser extent, NO<sub>2</sub>(O<sup>l</sup>) has a 0.67/-0.41 |e| spin/charge distribution in the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(O<sup>l</sup>) isomer. The calculated Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>–NO<sub>2</sub> binding energies are ΔH/ΔG = -22.2/-22.1 and -18.7/-13.9 kcal mol<sup>-1</sup> in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(Cs<sup>N</sup>) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/NO<sub>2</sub>(O<sup>l</sup>), respectively.

**Fig. 3** The calculated most energetically stable structures of NO<sub>2</sub> and N<sub>2</sub>O<sub>4</sub> adsorbed on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>, with their important geometry parameters (in Å).

Consequently, the acquired partial radical character of  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  in the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{Cs}^{\text{N}})$  complex significantly increases its  $\text{NO}_2$ -affinity, enabling strong coordination of another (second)  $\text{NO}_2$  radical to the  $\text{O}^{\text{t}}$ -site of polyoxoniobate and formation of the most thermodynamically favorable  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  singlet species. The calculated energy of the reaction  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{Cs}^{\text{N}}) + \text{NO}_2 \rightarrow \text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  is  $\Delta E/\Delta H/\Delta G = -55.8/-52.4/-35.9 \text{ kcal mol}^{-1}$ , while the energy of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{O}^{\text{t}}) + \text{NO}_2 \rightarrow \text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  reaction is  $\Delta E/\Delta H/\Delta G = -63.8/-61.5/-52.8 \text{ kcal mol}^{-1}$  (see ESI† for more details). Thus, removal of  $\text{NO}_2(\text{O}^{\text{t}})$  and/or  $\text{NO}_2(\text{Cs}^{\text{N}})$  from  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  with two  $\text{NO}_2$ -adsorbates requires greater energy than removing them from  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{O}^{\text{t}})$  and/or  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{Cs}^{\text{N}})$ . The overall energy of the reaction  $\text{Cs}_8\text{Nb}_6\text{O}_{19} + 2\text{NO}_2 \rightarrow \text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  is  $\Delta E/\Delta H/\Delta G = -77.4/-74.6/-58.0 \text{ kcal mol}^{-1}$  (see Table 1). To summarize, a relatively weak coordination of the first  $\text{NO}_2$  radical to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  at the Cs sites promotes stronger coordination of the second  $\text{NO}_2$  molecule at the  $\text{O}^{\text{t}}$  site of  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ . As a result, the coordination of the  $\text{NO}_2$  radicals to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  is substantially stronger than that of  $\text{CO}_2$ , yet slightly weaker than that of one  $\text{SO}_2$  molecule.

The reported highly stable  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  complex with two  $\text{NO}_2$  fragments can also be formed *via* N-N bond activation of the coordinated  $\text{N}_2\text{O}_4$  molecule by the polyoxometalate catalyst. The former pathway (*i.e.* stepwise addition of two  $\text{NO}_2$  radicals to polyoxoniobate) may be valid at ambient temperature, while the latter process may occur at low temperature. In this paper, we did not study the N-N activation barrier; however, we found that the complex  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  (see Fig. 3) lies significantly lower in energy than the  $\text{Cs}_8\text{Nb}_6\text{O}_{19} + \text{N}_2\text{O}_4$  dissociation limit, by  $\Delta E/\Delta H/\Delta G = 57.6/57.3/52.4 \text{ kcal mol}^{-1}$ , and  $\Delta E/\Delta H/\Delta G = 37.8/40.0/46.8 \text{ kcal mol}^{-1}$  lower than the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{N}_2\text{O}_4$  intermediate.

In order to better understand the factors impacting the strength of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2$  interaction, we also analyzed the geometry of the complex  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$ . As seen in Fig. 3, where we present the most important geometries of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{O}^{\text{t}})$ ,  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{Cs}^{\text{N}})$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  species (for full geometries of these species, see the ESI†), in  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$ , the Nb– $\text{O}^{\text{t}}$  bond is elongated to 2.47 Å; concurrently, the Nb– $\text{O}^{\text{IN}}$  bonds (which are 2.34, 2.44 and 2.02 Å in these complexes, respectively) and N– $\text{O}^{\text{t}}$  bonds (which are 1.28 and 2.25 Å in  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{NO}_2(\text{O}^{\text{t}})$ , respectively) are formed. As a result, the complex  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  has one  $\text{NO}_3^{-\delta}$  fragment ( $\delta = 0.4$ ) and one  $\text{NO}_2^{-\delta}$  fragment ( $\delta = 0.94$ ) coordinated to the Cs-cations.

Above, we have shown that: (1) at ambient temperatures, a relatively weak coordination of the first  $\text{NO}_2$  radical to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  confers partial radical character on the polyoxoniobate and promotes a stronger coordination of the second  $\text{NO}_2$  radical to form a stable diamagnetic  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  complex, and (2) at low temperatures, coordination of a weakly stable  $\text{N}_2\text{O}_4$  molecule to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  followed by facile N-N bond activation leads to the same  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  complex. Regardless of the formation mechanisms, in

$\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$ , the coordination of the  $\text{NO}_2$  radical positioned at  $\text{O}^{\text{t}}$  to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  is substantially stronger than that of  $\text{CO}_2$ , yet is slightly weaker than that of one  $\text{SO}_2$  molecule.

These conclusions from our computations are fully supported by experiments. As with  $\text{CO}_2$ , the adsorption of  $\text{NO}_2$  onto  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  was probed with the use of infrared spectroscopy. Fig. 4 shows spectra for the interaction between  $\text{NO}_2$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ . The adsorption of  $\text{NO}_2$  on the surface resulted in two infrared vibrational features – one at  $1668 \text{ cm}^{-1}$  and another at  $1240 \text{ cm}^{-1}$  (Fig. 4, i). These features are attributed to adsorbate N–O stretches as opposed to POM motions, which appear below  $1000 \text{ cm}^{-1}$ . Analysis of the calculated  $[\text{Cs}_8\text{Nb}_6\text{O}_{19}]\text{--NO}_2$  complexes suggests that the  $1668 \text{ cm}^{-1}$  feature is likely due to an asymmetric NO stretch originating from the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{N}_2\text{O}_4$  complex, which the calculations (unscaled) show to be at  $1813 \text{ cm}^{-1}$ . For the other  $\text{NO}_2$  complexes, the highest frequency NO stretch is found below  $1600 \text{ cm}^{-1}$ , *i.e.* at a lower frequency relative to the experimental peak. Taking into account the usual anharmonic correction, these modes will be found to be even further redshifted to lower frequencies. However, if we consider that the calculated asymmetric (strongly IR active) NO stretch of a free  $\text{NO}_2$  radical is  $1752 \text{ cm}^{-1}$ , and the known experimental value<sup>25</sup> is  $1618 \text{ cm}^{-1}$ , the resulting frequency scale factor of 0.92 brings the asymmetric NO stretch of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{N}_2\text{O}_4$  complex to exactly  $1668 \text{ cm}^{-1}$ . Moreover, if the measured 1668 and  $1240 \text{ cm}^{-1}$  peaks originate from the same thermal mixture of diamagnetic complexes, we expect that the  $1240 \text{ cm}^{-1}$  peak, which persists at higher temperatures (Fig. 4, iii), is due to the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  complex, which is much more stable to thermal perturbation than  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{N}_2\text{O}_4$ . The latter immediately transforms to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  upon N–N activation by heating. Indeed, there is a group of IR-active NO stretching motions in the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{t}})]$  complex in the  $1346$  to  $1361 \text{ cm}^{-1}$  ( $1238$  to  $1252 \text{ cm}^{-1}$  scaled) region, which captures the measured  $1240 \text{ cm}^{-1}$  peak.

Fig. 4 Infrared spectra recorded during and after the adsorption of  $\text{NO}_2$  onto  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  at 300 K. (i) Adsorption of 35 mTorr of  $\text{NO}_2$ . (ii) After  $\text{NO}_2$  evacuation. (iii) After  $\text{NO}_2$  evacuation and thermal treatment at 423 K.

Thus, we present two spectra (shown in Fig. 5); one corresponds to low temperature, Fig. 5(A), which is the sum of  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{N}_2\text{O}_4$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{I}})]$ , and one corresponds to high temperature, Fig. 5(B), which is pure  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{I}})]$ . The frequency axis is scaled by the same factor of 0.92. The calculation is consistent with experiments with regard to the disappearance of the  $1668\text{ cm}^{-1}$  peak and the persistence of the  $1240\text{ cm}^{-1}$  peak. However, the peak at  $1470\text{ cm}^{-1}$  (after scaling) in the calculated spectra, which is attributed to a local NO stretch of the  $\text{NO}_3$  unit in  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{I}})]$ , is absent in the room-temperature experiments. This suggests that the formation of  $\text{NO}_3$  requires a significant amount of thermal energy.

Furthermore, experiments clearly show that  $\text{NO}_2$  is strongly bound to the POM, *i.e.* the  $1240\text{ cm}^{-1}$  peak is present even after gas phase evacuation (Fig. 4, ii) and upon heating the POM to  $423\text{ K}$  (Fig. 4, iii). In fact, thermal treatment up to  $600\text{ K}$  was required to fully desorb the species, *i.e.* to remove  $\text{NO}_2$  radicals. This suggests that  $\text{NO}_2$  binds more strongly to the POM than  $\text{CO}_2$ , which is consistent with the computational data for the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{I}})]$  complex presented above (see Table 1 and the ESI†).

Thus, the data presented above show that in the presence of ambient gas molecules of  $\text{CO}_2$ ,  $\text{NO}_2$  and  $\text{SO}_2$ ,  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  will absorb these molecules more strongly than the water and GB molecules required for hydrolysis of Sarin (see Table 1). This is expected to impact the hydrolysis of Sarin by  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  in the following two ways: first, because the ambient gas molecules coordinate to catalytically active  $\text{O}^{\text{I}}$ -centers, they block these catalytically active centers, hindering water and Sarin coordination, and may alter the previously reported mechanism of Sarin hydrolysis by  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ . Second, the interaction of an ambient gas molecule with  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  may change the electronic properties of the polyoxoniobate: this is expected to only impact the calculated energetics of the Sarin hydrolysis and to not significantly change the nature of the previously reported intermediates and transition state structures.

Fig. 5 The calculated harmonic IR spectra (all in the NO stretch region), scaled by 0.92, of (A) the sum of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{N}_2\text{O}_4$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{I}})]$  species; (B) the pure  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/[\text{NO}_2(\text{Cs}^{\text{N}})\text{NO}_2(\text{O}^{\text{I}})]$  species.

Below, we test the first hypothesis by (a) studying the full potential energy surfaces of GB hydrolysis by  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$ , where  $\text{X} = \text{CO}_2$  and  $\text{SO}_2$ , and (b) comparing these new findings with our previous results on the same reaction in the absence of ambient gas molecules. For the sake of simplicity, we discuss in detail only the reaction mechanism (as well as the structures of the pre-reaction complexes, intermediates, transition states and products) for  $\text{X} = \text{CO}_2$  and compare these findings with those (previously reported) in the absence of ambient gas molecules. In addition, we briefly discuss, where appropriate, our findings for  $\text{X} = \text{SO}_2$  (full potential energy surfaces are available in the ESI†). The reactivities of the  $\text{NO}_2$  and other radical species coordinated to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  will be reported elsewhere.

## B. Hydrolysis of Sarin by $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$ species (where $\text{X} = \text{CO}_2$ and $\text{SO}_2$ )

As we have shown previously<sup>24</sup> and have briefly discussed above (see Scheme 1), Sarin hydrolysis by  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  is a multistep process, with coordination of a water molecule to the catalyst as the first step. The calculations (see Table 1) show that coordination of  $\text{H}_2\text{O}$  to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  to form  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{H}_2\text{O}$  is exothermic/exergonic by (presented as  $\Delta H/\Delta G$ )  $23.6/17.3\text{ kcal mol}^{-1}$ . In  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{H}_2\text{O}$ , the two hydrogens of the water molecule interact with one bridging ( $\text{O}^{\text{II}}$ ) and one terminal ( $\text{O}^{\text{I}}$ ) oxygen atom of the polyoxometalate.

Water molecule coordination to the adduct formed when  $\text{CO}_2$  (or  $\text{SO}_2$ ) binds to the  $\text{O}^{\text{I}}$ -center of  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  is a few  $\text{kcal mol}^{-1}$  less than that for “free”  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ ; the energies are  $-22.4/-11.9$  and  $-21.0/-9.7\text{ kcal mol}^{-1}$  for  $\text{X} = \text{CO}_2$  and  $\text{SO}_2$ , respectively. This effect is more pronounced for the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{SO}_2$  adduct than for  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{CO}_2$ . Furthermore, as seen in Fig. 6, the water coordination motif in  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{CO}_2/\text{H}_2\text{O}$  is different from that in  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{H}_2\text{O}$ : because  $\text{CO}_2$  occupies the  $\text{O}^{\text{I}}$ -position in  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{CO}_2$ , the  $\text{H}_2\text{O}$  molecule is H-bonded to one bridging ( $\text{O}^{\text{II}}$ ) and one  $\text{CO}$  ( $\text{O}^{\text{I}}$ ) oxygen atom (instead of  $\text{O}^{\text{I}}$ ). The calculated  $\text{O}^{\text{II}}-\text{H}^1$  and  $\text{O}^{\text{I}}-\text{H}^2$  bond distances are  $1.76$  and  $1.85\text{ \AA}$ , respectively.

Following the formation of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}/\text{H}_2\text{O}$  complex, the addition of Sarin to this intermediate occurs. Previously, we examined several approaches of Sarin to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  and found that nerve agent decomposition occurs when Sarin approaches the hydrated  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  segment with its  $\text{O}(\text{sp}^2)$  and  $\text{O}(\text{sp}^3)$  atoms (labeled in Fig. 6 and below as  $\text{O}^5$  and  $\text{O}^4$ , respectively).<sup>24</sup> The additional stabilization of the complex arises from the long-range  $\text{O}^4 \cdots \text{Cs}^3$  ionic interaction. Thus, for the purposes of modeling the decomposition of Sarin in the presence of carbon and sulfur dioxide, it is sufficient to examine the most energetically favorable pathway, similar to that previously reported for the case with no ambient gas molecules. In keeping with the previously established shorthand notation, the pre-reaction complex of this reaction pathway is labeled as R-F\_X.

The present calculations show that the coordination of Sarin (GB) to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}/\text{H}_2\text{O}$  is exothermic by  $-18.0/-2.4$  and  $-17.4/-3.8\text{ kcal mol}^{-1}$  for  $\text{X} = \text{CO}_2$  and  $\text{SO}_2$ , respectively. Inspection of the structure of the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}/\text{H}_2\text{O}/\text{GB}$ , R-F\_X, intermediate reveals a non-covalently bonded  $[\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{CO}_2/\text{H}_2\text{O}]\text{-GB}$  complex. For example, as seen in Fig. 6, in contrast to

Fig. 6 Calculated pre-reaction complexes, transition states and products of GB hydrolysis by Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub> (i.e. the reaction Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub> + H<sub>2</sub>O + GB → R-F\_CO<sub>2</sub> → TS-F\_CO<sub>2</sub> → P5-F\_CO<sub>2</sub>) and their important geometry parameters (in Å). Similar structures for X = SO<sub>2</sub> are presented in the ESI.†

the coordination of GB to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/H<sub>2</sub>O, in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>/H<sub>2</sub>O/GB, the nerve agent is coordinated to one of the Cs centers of the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-core with its P=O<sup>4</sup> double bond. Several H-bonds also exist between the GB ligand and the [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>/H<sub>2</sub>O]-fragment. In this complex, the calculated Cs<sup>3</sup>-O<sup>4</sup> bond distance is 3.13 Å and the nascent P-O<sup>3</sup>(OH<sub>2</sub>) bond distance is 3.12 Å.

In the next step, hydrolysis of the coordinated water molecule occurs between the coordinated gas molecule X, the bridging oxygen (O<sup>μ</sup>) of the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-core and the phosphorus center of Sarin. The transition state associated with this process, TS-F\_CO<sub>2</sub>, is shown in Fig. 6 (for TS-F\_SO<sub>2</sub>, see the ESI.†). As seen in this figure, at TS-F\_CO<sub>2</sub>, the breaking O<sup>3</sup>-H<sup>1</sup> bond of the water molecule is elongated to 1.16 Å, and the forming O<sup>μ</sup>-H<sup>1</sup> bond distance becomes 1.25 Å. In addition, Nb<sup>1</sup>-O<sup>μ</sup> and Nb<sup>2</sup>-O<sup>μ</sup> bonds are slightly elongated and the Cs<sup>3</sup>-O<sup>4</sup> bond is slightly shortened. Importantly, the Cs<sup>3</sup>-center of the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> core also interacts with the oxygen (O<sup>3</sup>) of water and provides additional support for hydrolysis. Here, the other coordinates of interest are the P-O<sup>3</sup>(H<sub>2</sub>O) bond and the P-F bond.

As seen in Fig. 6, P-O<sup>3</sup>(H<sub>2</sub>O) undergoes a major reduction from 3.12 Å in R-F\_CO<sub>2</sub> to 1.96 Å in TS-F\_CO<sub>2</sub>. Its P-F counterpart, located *trans* to the water-activated molecule, extends from the typical single bond in R-F\_CO<sub>2</sub>, with an increase from 1.62 Å to 1.71 Å in TS-F\_CO<sub>2</sub>. Similar geometry changes at the hydrolysis transition state were observed for X = SO<sub>2</sub> (see the ESI.†). As seen in Fig. 7, the calculated ΔE/ΔG barrier heights relative to

R-F\_X are 7.8/7.5 and 8.4/8.8 kcal mol<sup>-1</sup> for X = CO<sub>2</sub> and SO<sub>2</sub>, respectively. These values are slightly larger than the values of 6.8/6.1 kcal mol<sup>-1</sup> calculated for the reaction in the absence of these ambient gas molecules; this suggests that common battlefield contaminants may impair the hydrolytic decomposition of nerve agents under operational conditions.

The hydrolysis product is a pentacoordinated-phosphorus complex P5-F\_X with a trigonal bipyramidal structure around the central phosphorus atom. In our previous paper, we showed that this intermediate exhibits multiple isomeric forms.<sup>24</sup> Here, we discuss only the energetically most favorable form, which is directly connected to the transition state TS-F\_X. For example,

Fig. 7 Potential energy profile of the hydrolysis of Sarin (GB) by Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X(O<sup>t</sup>), where X = CO<sub>2</sub> or SO<sub>2</sub>. ΔE and ΔG are the changes in the electronic and Gibbs free energies and are calculated relative to the reactants Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X(O<sup>t</sup>) + H<sub>2</sub>O + GB.

as seen in Fig. 6, the formed P–O<sup>3</sup> bond in P5-F\_CO<sub>2</sub> contracts to 1.79 Å, while its P–F counterpart, located *trans* to the activated water molecule, extends to 1.76 Å. The broken O<sup>3</sup>–H<sup>1</sup> bond is elongated to 1.64 Å and the Nb<sup>1</sup>–O<sup>ii</sup> and Nb<sup>2</sup>–O<sup>ii</sup> bonds are elongated to 2.20 and 2.13 Å, respectively. Concurrently, the Cs<sup>3</sup>–O<sup>3</sup> bond of 3.11 Å is formed to provide additional stabilization to the pentacoordinated-phosphorus complex, similar to that previously reported in P5-F.<sup>24</sup> Based on the calculated Mulliken charge distribution, the resulting P5-F\_X complexes can be labeled as a [(GBOH<sup>−</sup>)(Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>H/X)]<sup>+</sup> ion-pair system.

As shown in Fig. 7, the hydrolysis of Sarin, *i.e.* the reaction Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X + H<sub>2</sub>O + GB → R-F\_X → TS-F\_X → P5-F\_X for X = none, CO<sub>2</sub> or SO<sub>2</sub>, is exergonic by −50.1/−27.9, −38.8/−11.1 and −40.5/−14.7 kcal mol<sup>−1</sup> (presented as ΔH/ΔG) and proceeds over energy barriers of 6.8/6.1, 7.5/7.5 and 8.4/8.8 kcal mol<sup>−1</sup> (calculated relative to the pre-reaction intermediate R-F\_X), respectively. The reaction R-F\_X → TS-F\_X → P5-F\_X is exothermic for X = none and SO<sub>2</sub> by 6.8/6.4 and 0.4/1.2 kcal mol<sup>−1</sup>, respectively, but is endothermic by 3.4/3.2 kcal mol<sup>−1</sup> for X = CO<sub>2</sub>. These energy values allow us to conclude that the presence of ambient gas molecules increases the energies of the stationary points relative to the asymptote of the reactants. This is likely the result of a different charge distribution on Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X relative to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>, where X acquires a net negative charge of 0.8 to 0.7 |e|, as we showed above. Furthermore, X coordinates to the O<sup>i</sup> reactive center and disables its hydrolytic activity. The presence of ambient gases increases the hydrolysis barrier by 1.0 to 2.5 kcal mol<sup>−1</sup>, and this change in the energy barrier is closely associated with the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>–X complexation energy: the stronger the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>–X bond, the higher the barrier for Sarin hydrolysis.

### C. Pentacoordinated P5-F\_X intermediate dissociation

Once the pentacoordinated P5-F\_X species is formed, the reaction can proceed along several paths, as discussed in our previous paper.<sup>24</sup> In order to evaluate the role of the catalyst in the course of the reaction, as above, here we discuss in detail only those pathways that directly involve the catalyst. These are the HF and isopropanol elimination and, ultimately, desorption pathways. The accompanying products of these paths are isopropyl methyl phosphonic acid (i-MPA) and methyl phosphonofluoridic acid (MPFA), respectively. It is evident that in order to form HF or isopropanol, protonation of the fluoride or oxygen centers of the isopropoxy ligand is required. Furthermore, in order to facilitate regeneration of the catalyst, the ultimate proton source should be the O<sup>ii</sup>H<sup>1</sup>-group of the [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>H/X]<sup>+</sup> cation. However, these processes are expected to be very complex and may proceed *via* multiple mechanisms. One of these processes could involve any surrounding water molecules, which are expected to be present in real experimental conditions. In this mechanism, a water molecule located close to the fluoride or oxygen atoms of the isopropoxy ligand is expected to donate its proton to these groups (to form HF and/or isopropanol, respectively) and compensate by removing the proton from the O<sup>ii</sup>H<sup>1</sup>-group of the catalyst *via*

a H-bonding network. This process depends on multiple factors (including, but not limited to, the concentration of water in the system and the reaction temperature) and was not studied in this paper.

Another possible mechanism of HF and/or isopropanol formation is direct removal of the proton from the O<sup>ii</sup>H<sup>1</sup>-group of the catalyst by the fluoride and/or isopropoxide ligands, respectively. As shown previously for the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> catalyst (*i.e.*, in the absence of ambient gas molecules),<sup>24</sup> these processes occur with very small energy barriers which have no contribution to the overall outcome of the decontamination reaction but lead to the most energetically stable intermediates, Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-(i-MPA)-HF and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-(MPFA)-(i-POH), respectively (see Fig. 8). Here, we performed an extensive search to locate the transition states TS2-F\_HF\_X and TS2-F\_(i-POH)\_X that lead to either HF and i-MPA or isopropanol (i-POH) and MPFA from the most stable pentacoordinated intermediate P5-F\_X (where X = CO<sub>2</sub> or SO<sub>2</sub>). Ultimately, we were able to locate only the TS2-F\_(i-POH)\_X transition state (see Fig. 8). The search for the HF formation transition state TS2-F\_HF\_X was unsuccessful and always led to either the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA)-HF intermediate, its derivative F<sup>−</sup>⋯H<sup>+</sup>⋯O<sup>ii</sup> intermediate, or the pre-reaction complex P5-F\_X. For example, in Fig. 8, we present the intermediates, transition states and products involved in pentacoordinated P5-F\_CO<sub>2</sub> intermediate dissociation alone, with their important geometry parameters (for those of X = SO<sub>2</sub>, see the ESI<sup>†</sup>). The relative energies of these species, calculated from the P5-F\_X pre-reaction complex, are given in Fig. 9.

As seen in Fig. 8, at the transition state TS2-F\_(i-POH)\_CO<sub>2</sub> associated with the formation of i-POH and MPFA, the activated P–O<sup>5</sup>(Osp<sup>2</sup>) bond extends to 2.19 Å from 1.68 Å in P5-F\_CO<sub>2</sub>, with simultaneous formation of a double H-bond network (O<sup>5</sup>–H<sup>1</sup> = 1.63 Å and O<sup>1</sup>–H<sup>2</sup> = 1.57 Å) as a precursor to the

Fig. 8 The calculated transition states, intermediates and products of the dissociation of pentacoordinated P5-F\_CO<sub>2</sub> (*i.e.* reactions: P5-F\_CO<sub>2</sub> → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>-(MPFA)-(i-POH) → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub> + MPFAH + (i-POH) and P5-F\_X → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>-(MPFA)-HF → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub> + MPAH + HF) with their important geometry parameters (in Å). Similar structures for X = SO<sub>2</sub> are presented in the ESI<sup>†</sup>.

Fig. 9 Potential energy profiles of the decomposition reaction of pentacoordinated-phosphorus intermediate P5-F\_X, where X = CO<sub>2</sub> and SO<sub>2</sub> (i.e. reactions: P5-F\_X → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(MPFA)-(i-POH) → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X + MPFAH + (i-POH) and P5-F\_X → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(MPA)-HF → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X + MPFAH + HF). ΔE and ΔG are the changes in the electronic and Gibbs free energies and are calculated relative to the reactants Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X(O<sup>t</sup>) + H<sub>2</sub>O + GB.

charge-preserving double proton transfer. In other words, as the proton of the O<sup>H</sup>H<sup>1</sup>-group moves to Sarin, the proton on the PO<sup>3</sup>H<sup>1</sup> group of Sarin migrates back to the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-core to form [HXO]<sup>t</sup>, where X = CO<sub>2</sub>. As a result, the formed P-O<sup>3</sup>(H<sub>2</sub>O) bond is shortened from 1.79 Å in P5-F\_CO<sub>2</sub> to 1.61 Å in the transition state.

As seen in Fig. 9, the calculated energy barriers from P5-F\_X are 7.0/7.6, 5.4/5.4 and 3.6/6.5 kcal mol<sup>-1</sup> for X = none, CO<sub>2</sub> and SO<sub>2</sub>. Thus, the presence of these gas molecules in the reaction mixture slightly reduces the pentacoordinated P5-F\_X intermediate dissociation barrier (by 2 to 4 kcal mol<sup>-1</sup>). Furthermore, the changes in the i-POH and MPFA formation energy barriers correlate with the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-X complexation energy: the stronger the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-X bond, the smaller the i-POH and MPFA formation energy barriers.

Comparison of the calculated energetics for the dissociation of the pentacoordinated intermediate with those for hydrolysis (i.e. formation of the pentacoordinated intermediate) show that, in general, the hydrolysis step is a rate-determining step for all reported species, and the presence of ambient gas molecules increases this energy barrier only slightly, by 2 to 4 kcal mol<sup>-1</sup>. Furthermore, the height of this rate-determining energy barrier correlates with the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-X complexation energy: the stronger the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>-X bond, the more difficult the hydrolysis of GB by the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> catalyst.

#### D. Catalyst regeneration

Thus, the facile dissociation of the P5\_F\_X species, as reported previously for P5\_F, yields HF and i-MPA and/or i-POH and MPFA products. All these species are initially bound to Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>, as shown in Fig. 8 for X = CO<sub>2</sub> and the ES1<sup>‡</sup> for X = SO<sub>2</sub>. For example, in the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>-(i-MPA)-HF complex, the (i-MPA)-fragment forms a hydrogen bond with the O<sup>H</sup> and OH-unit of the HOCOO<sup>t</sup> fragment, respectively. The HF molecule, on the other hand, in the presence of an X molecule,

prefers to form an [F<sup>-</sup>⋯H<sup>+</sup>] ion-pair prior to dissociation. Similarly, in the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub>-(MPFA)-(i-POH) complex, the (i-POH) molecule and MPFA-fragment are hydrogen bonded to another O<sup>t</sup> atom and the OH-unit of the HOCOO<sup>t</sup> fragment, respectively; the calculated H<sup>1</sup>-O<sup>6</sup> and O<sup>3</sup>-H<sup>2</sup> bond distances are 1.73 and 1.67 Å, respectively. In addition, there are electrostatic interactions between the O center of the isopropanol molecule and two Cs cations of the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/CO<sub>2</sub> core, with Cs<sup>1</sup>-O<sup>5</sup> and Cs<sup>3</sup>-O<sup>5</sup> bond distances of 3.19 Å and 3.31 Å, respectively. The formed P-O<sup>3</sup> fragment also interacts with the Cs<sup>1</sup>-center, with a Cs<sup>1</sup>-O<sup>3</sup> distance of 3.16 Å.

As seen in Fig. 9, the formed Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA-(i-POH) is the energetically lowest structure on the potential energy surface of the entire GB hydrolysis and decontamination reaction by Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub> both in the absence and presence of ambient gas molecules. The intermediate Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA)-HF is found to be only slightly higher in energy. As we mentioned previously,<sup>24</sup> the high stability of these intermediates is due in part to the strong hydrogen bonds between the adsorbates and the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-core; however, it is also due to the additional stabilizing interactions between the Cs counter-ions and the electronegative atoms of the nerve-agent fragments.

Desorption of HF and isopropanol from Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA)-HF and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA-(i-POH) requires 15.2/12.7 and 20.0/5.3 kcal mol<sup>-1</sup> energy, respectively, for X = CO<sub>2</sub>. Dissociation of HF and isopropanol only slightly modifies the geometries of the products Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA fragments (for example, see Fig. 8 for X = CO<sub>2</sub>) compared with the Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA)-HF and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA-(i-POH) adducts; therefore, this will not be discussed in detail.

However, both i-MPA in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA) and MPFA in Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA are strongly bound to the protonated [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X]H<sup>+</sup>-core. Thus, regeneration of the catalyst requires deprotonation of the [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X]H<sup>+</sup>-core and protonation of the phosphonic acids i-MPA and MPFA. This step of the reaction, which forms a final decontaminated form of the GB and re-generated catalyst, is found to be highly endothermic/endergonic, i.e. 6.4/6.5 and 2.8/1.9 kcal mol<sup>-1</sup> for i-MPAH and MPFAH formation, respectively. Overall, the last steps of the reaction, i.e. the reactions Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-(i-MPA)-HF → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X + HF + (i-MPAH) and Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X-MPFA-(i-POH) → Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X + (i-POH) + MPFAH, are highly prohibitive and require energies of 80.3/60.2 (X = none), 64.4/36.3 (X = CO<sub>2</sub>), and 66.0/39.4 (X = SO<sub>2</sub>) kcal mol<sup>-1</sup> and 81.0/60.4 (X = none), 71.2/43.6 (X = CO<sub>2</sub>), and 63.3/36.4 (X = SO<sub>2</sub>) kcal mol<sup>-1</sup>, respectively. Furthermore, deprotonation of the [Cs<sub>8</sub>Nb<sub>6</sub>O<sub>19</sub>/X]H<sup>+</sup>-core and protonation of the phosphonic acids i-MPA and MPFA is expected to be very complex and may proceed *via* several pathways depending on the reaction conditions. One of these may involve any surrounding water molecules, in real experimental conditions, *via* a concerted protonation-deprotonation mechanism involving the hydrogen-bonded water-based network. However, this process depends on multiple factors (including, but not limited to, the concentration of water in the system and the reaction temperature) and was not studied in this paper. We also failed to locate a transition state associated with the direct deprotonation of

$[\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}]\text{H}^+$  and protonation of the phosphonic acids because of the high stability of the corresponding pre-reaction complexes  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}(\text{i-MPA})$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X-MPFA}$ . The solution to this issue requires special comprehensive experimental and computational studies, which are in progress.

## Conclusions

This paper, for the first time, addresses the impact of environmentally-significant ambient gas molecules,  $\text{NO}_2$ ,  $\text{CO}_2$  and  $\text{SO}_2$ , on the structure, stability and decontamination activity of a basic polyoxometalate species. Specifically,  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  in the presence of these gases has been studied in depth by complementary computational and experimental approaches. It was found that:

(1)  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  absorbs ambient gas molecules of  $\text{X} = \text{CO}_2$ ,  $\text{NO}_2$  and  $\text{SO}_2$  more strongly than it absorbs water or Sarin (GB) molecules. The calculated  $\text{Cs}_8\text{Nb}_6\text{O}_{19}\text{-X}$  binding energy follows the trend for  $\Delta G (\text{X} = \text{CO}_2) < \Delta G (\text{NO}_2) < \Delta G (\text{SO}_2)$ .

(2) The impacts of the diamagnetic  $\text{CO}_2$  and  $\text{SO}_2$  molecules on polyoxoniobate  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  are fundamentally different than that of the  $\text{NO}_2$  radical. At ambient temperatures, weak coordination of the first  $\text{NO}_2$  radical to  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  confers partial radical character on the polyoxoniobate and promotes a stronger coordination of the second  $\text{NO}_2$  radical to form a stable diamagnetic  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/(\text{NO}_2)_2$  species; meanwhile, at low temperatures,  $\text{NO}_2$  radicals form weakly stable dinitrogen tetraoxide ( $\text{N}_2\text{O}_4$ ), which interacts weakly with  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$ .

(3) Similar to the case without ambient gas molecules, reported previously,<sup>24</sup> in the presence of X, GB hydrolysis by  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$  proceeds *via* general base hydrolysis involving: (a) adsorption of water and the nerve agent on the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}$  catalyst, (b) concerted hydrolysis of the adsorbed water molecule on a basic oxygen atom of the polyoxoniobate and nucleophilic addition of the nascent OH group to the phosphorus center of the nerve agent, (c) rapid reorganization of the resulting pentacoordinated-phosphorus intermediate followed by dissociation of either HF or isopropanol with formation of POM-bound isopropyl methyl phosphonic acid (i-MPA) or methyl phosphonofluoridic acid (MPFA), respectively.

(4)  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  adsorbs ambient gas molecules X at its basic  $\text{O}^t$  (or  $\text{O}^h$ ) reactive centers, which shields them from involvement in the base hydrolysis. As a result, one of the O centers of the coordinated ambient gas molecule becomes an active hydrolysis center. This increases the energies of the stationary points relative to the asymptote of the reactants and increases the hydrolysis barrier. These changes are closely correlated with the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}\text{-X}$  complexation energy; the stronger the  $\text{Cs}_8\text{Nb}_6\text{O}_{19}\text{-X}$  bond, the higher the barrier for Sarin hydrolysis.

(5) The most energetically stable products of the GB hydrolysis and decontamination reaction are  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X-MPFA}(\text{i-POH})$  and  $\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}(\text{i-MPA})\text{-HF}$  both in the absence and presence of ambient gas molecules. The high stability of these intermediates is due in part to the strong hydrogen bonds between the adsorbates and the protonated  $[\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}/\text{H}]^+$ -core and to interactions between the Cs counterions and the electronegative atoms of the adsorbates.

(6) Desorption of HF or/and (i-POH) and regeneration of the catalyst requires deprotonation of the  $[\text{Cs}_8\text{Nb}_6\text{O}_{19}/\text{X}/\text{H}]^+$ -core with protonation of the phosphonic acids i-MPA and MPFA. Regeneration of the catalyst is a highly endergonic process and is the rate-limiting step for GB hydrolytic decontamination, both in the absence and presence of ambient gas molecules.

## Notes

### A. Computational and experimental procedures

**A1. Computational methodology.** A major computational challenge in the present work is to properly describe the non-covalent interactions involving the various ions in the systems studied: the  $\text{Cs}^+$  counter-cations,  $[\text{Nb}_6\text{O}_{19}]^{8-}$  with its large negative charge, and the  $\text{H}^+$  and  $\text{OH}^-$  ions resulting from heterolytic water dissociation. These interactions are expected to be well described by the M06-L density functional,<sup>27</sup> a pure density functional designed for transition metal bonding and non-covalent interactions. Therefore, all presented calculations have been carried out with the M06-L density functional, as implemented in the Gaussian09 code.<sup>28</sup> In these calculations, we used the 6-31++G(d,p) basis set for the elements S, P, F, O, C, H and the LanL2dz basis set with corresponding Hay-Wadt effective core potentials for Nb and Cs, as implemented in Gaussian09. The sets of diffuse functions (++) were added specifically to obtain proper descriptions of the diffuse charge densities and long-range interactions. All reported stationary points were confirmed to have either all real frequencies (minima) or one imaginary frequency (transition states). The latter were further verified to connect the corresponding minima by IRC calculations. All reported enthalpy and Gibbs free energies were computed at a temperature of 298.15 K and 1 atm pressure.

**A2. Experimental methodology.** The synthesis of  $\text{Cs}_8\text{Nb}_6\text{O}_{19}\cdot 14\text{H}_2\text{O}$  followed a known literature procedure. A solution of cesium hydroxide (14.6 g, 50% by weight) was heated to 90 °C in an Erlenmeyer flask. 5 g of hydrous, amorphous niobium oxide was added in small portions, with full dissolution of each portion before addition of the subsequent portion. Evaporative crystallization yielded giant hexagonal crystals.

Infrared spectroscopic experiments were performed in a stainless-steel high-vacuum chamber with a base pressure of  $\sim 1 \times 10^{-8}$  Torr. The  $\text{Cs}_8\text{Nb}_6\text{O}_{19}$  sample was pressed, as a 7 mm diameter disk, into a tungsten grid, which was then clamped onto a sample mount coupled to a precision manipulator. An empty region of the grid was used to monitor the gas phase species in the chamber and was also employed as a background for surface adsorption and desorption studies. The grid was resistively heated, and the temperature was monitored *via* a K-type thermocouple spot-welded adjacent to the sample. A PID controller mediated the sample temperature to within  $\pm 1$  K. Details of the vacuum chamber and sample mount can be found in a previous publication.<sup>29</sup> An FTIR spectrometer (Thermo, Nicolet, Nexus 470 FTIR) with an external liquid- $\text{N}_2$ -cooled MCT-A detector and a spectral resolution of  $2 \text{ cm}^{-1}$  was used for collection of the infrared spectra.
