Herein we have investigated the ability of the (6,6) MoS₂-nanotube (NT) to sense environmentally hazardous electrophilic and nucleophilic gases using density functional theory (DFT). CO, CO₂, H₂O and NH₃ gases were chosen for adsorption on the (6,6) MoS₂-NT and different adsorption parameters such as adsorption energy, projected density of states (PDOS), band structure and structural changes after adsorption were evaluated. Nucleophilic gases NH₃ and H₂O showed a fairly high amount of electron density transfer from gas molecules to the NT while the opposite trend was realized for electrophilic gases CO and CO₂. Among the four gases, H₂O has the highest amount of adsorption energy (−1.74 eV) and a moderately high amount of charge transfer from H₂O to the NT. Gas sensing behaviour was further rationalized from the enhanced *I*–*V* characteristics of gas adsorbed nanotubes compared to pristine ones. Analysis of results revealed that the (6,6) MoS₂-NT showed a decent level of gas sensing properties towards CO, CO₂, H₂O and NH₃ gases, and high selectivity for H₂O makes the MoS₂-NT superior to previously reported MoS₂-monolayer in this matter. These results suggest the possibility of fabrication of highly efficient MoS₂-NT based gas sensors for environmentally hazardous gases.

Introduction

Toxic and carcinogenic gases are the main contributors to air pollution. These gases can affect both human health and the environment directly or indirectly. Oxides of carbon, nitrogen and other elements, along with methane, ammonia, CFCs and water vapour in air are mainly responsible for air pollution leading to various pulmonary and other diseases. Global warming is another issue which we cannot ignore any more. In this context, gas sensors which are cost effective, easy to use and require low power to operate are very promising candidates. Lots of research endeavours to discover and design such efficacious gas sensing materials are being carried out.

Use of 2D-materials such as graphene, hexagonal boron nitride nanosheets and carbon NTs as gas sensing agents is decades old.^{1–4} Graphene oxide can also be used as a gas sensor.⁵ Graphene quantum dots have shown potential sensing ability for toxic gases.⁶ In the last few years, 2D-materials of transition metal dichalcogenides (TMDs) *viz.* MX₂ (X = S, Se, Te) have drawn attention due to their potential gas sensing properties.⁷ Among these TMDs, MoS₂ has gas sensing ability

comparable to graphene^{8,9} and WS₂ can sense both toxic and non-toxic gases.^{10,11}

Among the 2D-transition metal dichalcogenides (TMDs), MoS₂ has evoked keen interest to the researchers due to its use in various fields *e.g.* optics, microbiology, catalysis, electrical appliances, energy conversion, gas sensing and lubrication.^{7,12–17} Both bulk and single-layer MoS₂ showed semiconducting nature with an indirect band gap of 1.23 eV and 1.8 eV, respectively.^{18,19} In MoS₂, the Mo-atom is sandwiched between two S-atoms through covalent bonds, while the monolayers are held together by weak van der Waals forces.²⁰ MoS₂ monolayer plays a key role in adsorbing and detecting gases such as NH₃, NO, NO₂, CO, H₂O, CO₂, CH₄, *etc.* 7–9, which are hazardous to both the environment and human health. The adsorption behaviour of MoS₂ monolayer is also explained by measuring the electronic transport properties of gas adsorbed MoS₂ monolayer. The gas sensing ability of MoS₂@gas monolayer is explained by changes in the rectification behaviour.¹¹ The adsorption of CO and H₂ gases on MoS₂ monolayer by creating sulphur vacancies, *i.e.* by defective MoS₂ monolayer, results in enhanced catalytic activity.²⁰ The adsorption power of MoS₂ monolayer was found to be enhanced by silver functionalization.²¹ Transition metal (V, Nb, Ta, and Ni) doped MoS₂ monolayer additionally showed potential gas adsorption properties.^{22,23} The effect of applied electric field on gas sensing by MoS₂ monolayer has also been reported.²⁴

Semiconducting MoS₂-NTs have a graphitic honeycomb structure. Single walled MoS₂-NTs can be synthesized by

† Electronic supplementary information (ESI) available. See DOI: 10.1039/d0na01037e

heating ammonium thiomolybdate²⁵ or by applying the catalytic transport of C₆₀ with MoS₂ powder.²⁶ It has generally two forms: (i) armchair (*n,n*) and (ii) zigzag (*n,0*).²⁴ Among these two forms, the armchair (*n,n*) MoS₂-NT shows an indirect band gap whereas the zigzag form shows a direct band gap. For the (*n,n*) MoS₂-NT, the band gap increases with the increase in the magnitude of *n*.²⁷ MoS₂-NT systems can sense NH₃ and NO₂ gases.²⁸ There are several reports on the variation of gas sensing properties of MoS₂-monolayer along with some other TMD materials, but the atomistic description of gas sensing ability of MoS₂-NTs is scarce.^{5,29,30} In the present work, we have made a comprehensive analysis of the adsorption behaviour and gas sensing ability of the (6,6) MoS₂-NT. Compared to other armchair (8,8; 10,10; 12,12; 14,14 with band gaps of 0.496, 0.783, 0.954, and 1.079 eV, respectively) and zig-zag (10,0; 12,0; 14,0 with band gaps of 0.225, 0.405, and 0.615 eV, respectively) MoS₂-NTs, the (6,6) NT possesses a lower band gap (0.19 eV).²⁷ So modulation of the electronic properties by adsorption of different gases can be achieved more easily involving the (6,6) NT. Furthermore, the results of adsorption of CO, CO₂, NH₃ and H₂O on the (6,6) MoS₂-NT are compared to those on 2D MoS₂-monolayer (ML). Surprisingly, it was found that the MoS₂-NT can act as a better gas sensing agent as compared to MoS₂-monolayer. This is verified from the binding energy analysis and explained by changes in the physical and electronic structure and *I*-*V* characteristics of the gases after adsorption.

Methodology

In the present work, the (6,6) MoS₂ armchair NT has been chosen for the adsorption of CO, CO₂, NH₃ and H₂O gases. A double- ζ plus (DZP) function basis set and a mesh cut-off of 300

Ry at 300 K electronic temperature were considered for geometry optimization. The Perdew–Burke–Ernzerhof (PBE)³¹ type generalized gradient approximation (GGA) exchange–correlation functional is used in all calculations, as implemented in the SIESTA program suite.^{32,33} Though the PBE functional underestimates the band gap, the results offered by the PBE functional are quite reasonable and cost effective as demonstrated by previous reports.^{34,35} The density matrix convergence criterion is set at 10^{−4}. The conjugate gradient method is used to stabilize all atoms until the maximum tolerance force reached a value less than 0.01 eV Å^{−1}. A 1 × 1 × 6 Monkhorst–Pack *k*-grid with a vacuum more than 20 Å in the *x* and *y* directions is applied in order to decouple the adjacent mirror images. In the present study, a single gas molecule was considered for adsorption on the NT to avoid spurious interactions between two neighbouring adsorbate gases. The adsorption energies of the gases are calculated using the following equation:

$$E_{\text{ads.}} = E_{\text{nanotube+gas}} - E_{\text{nanotube}} - E_{\text{gas}} \quad (1)$$

where $E_{\text{nanotube+gas}}$ indicates the total energy of the composite system and E_{nanotube} and E_{gas} are the energies of the MoS₂-NT and the studied gases, respectively.

Furthermore, to understand the adsorption mechanism, electronic transport properties of the MoS₂-NT and MoS₂-NT@gases have been studied by applying density functional theory combined with non-equilibrium Green's function as implemented in TransSIESTA.³⁴ A similar correlation functional was used to calculate the transport properties as above. To study the transport properties of the MoS₂-NT and MoS₂-NT@gas, three regions were considered *viz.* the left hand electrode (LHE,

Fig. 1 Top view of the MoS₂-NT and gas adsorbed MoS₂-NT (a) MoS₂-NT, (b) MoS₂-NT@CO, (c) MoS₂-NT@CO₂, (d) MoS₂-NT@NH₃, and (e) MoS₂-NT@H₂O.

containing 36 atoms), right hand electrode (RHE, containing 36 atoms) and scattering region (SR, containing 140 atoms in the MoS₂-NT, 142 atoms in MoS₂-NT@CO, 143 atoms in MoS₂-NT@CO₂, 144 atoms in MoS₂-NT@NH₃ and 143 atoms in MoS₂-NT@H₂O). Applying the Landauer-Buttiker formula under finite bias (V_b), the amount of current passed was calculated within the energy bias window from $-eV_b/2$ to $+eV_b/2$ by integrating the transmission function $T(E, V_b)$.

$$I(V_b) = \frac{2e}{h} \int_{-\infty}^{+\infty} T(E, V_b) [f_L(E - \mu_L) - f_R(E - \mu_R)] dE \quad (2)$$

where f_L and f_R are the Fermi-Dirac distribution functions for the left and right electrodes, respectively and μ_L and μ_R are the chemical potentials of the left and right electrodes, respectively and $eV_b = \mu_L - \mu_R$. To understand the I vs. V characteristics, a finite bias from -1 to 1 V was used keeping a bias spacing of 0.1 eV.

Results and discussion

The optimized lattice parameter for the (6,6) MoS₂-NT was found to be 3.23 \AA , which is much better than that found in previous theoretical studies.²⁷ Optimized structures of the (6,6) MoS₂-NT itself and with CO, CO₂, H₂O and NH₃ adsorbed on it are shown in Fig. 1a–e. Four different adsorption sites *viz.* the top of the hexagon (the H-site), top of the outer S-atom (the S-site), top of the Mo-atom (the M-site) and top of a Mo–S bond site (the B-site) on the surface of the MoS₂-NT were considered for gas adsorption. We note that for CO and CO₂ adsorption, the preferable sites are the H-site and S-site, respectively, while for NH₃ and H₂O the preferable site is the M-site.

Fig. 2a shows the adsorption energies of the composite systems along with the favoured binding sites (values are available in Table S1†). The MoS₂-NT@CO system has an adsorption energy of -0.44 eV at the H-site; for the MoS₂-

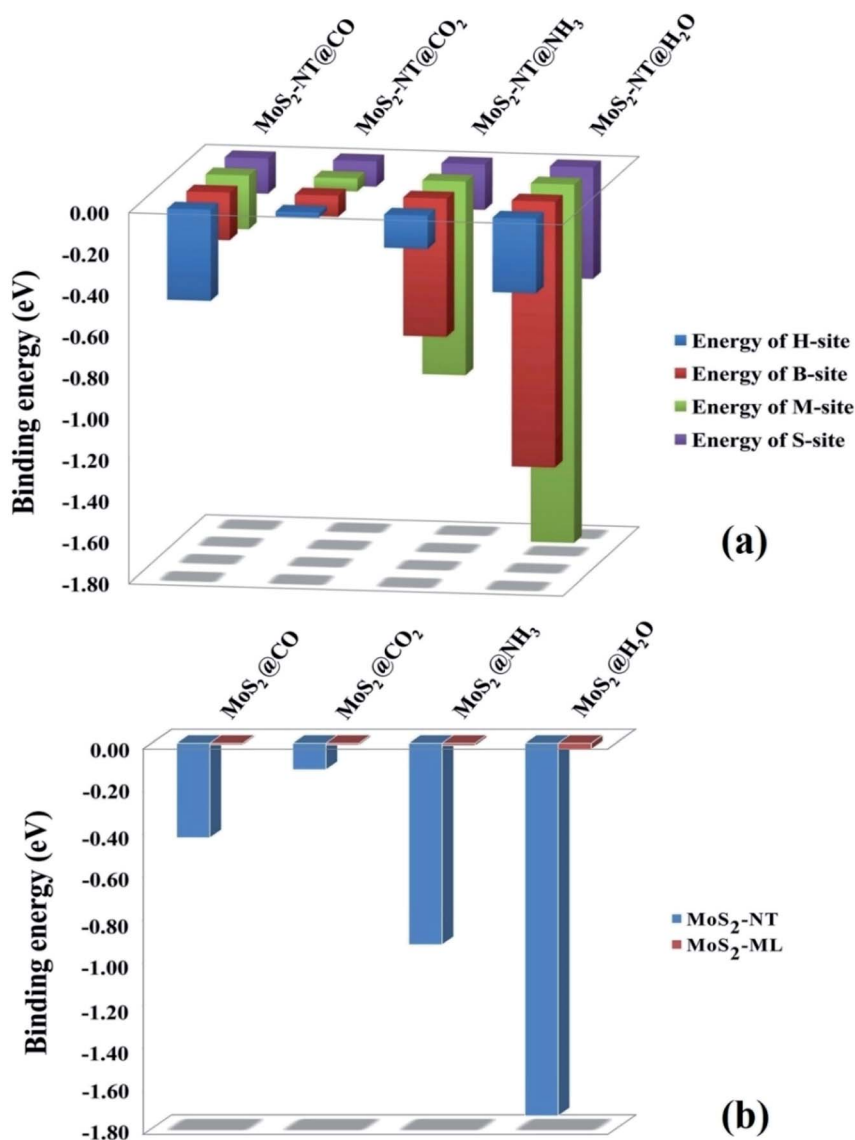

Fig. 2 (a) Adsorption energies of gases at different sites of the MoS₂-NT, (b) adsorption energies of gases with the MoS₂-NT and MoS₂-ML.⁷

NT@CO₂ system, the adsorption energy at the S-site is -0.12 eV and for MoS₂-NT@NH₃ and MoS₂-NT@H₂O, where adsorption is on the M-site, the adsorption energy values are -0.94 eV and -1.74 eV, respectively.

The negative adsorption energies reveal that the adsorption is purely exothermic and therefore energetically favourable in all cases. Fig. 2b shows the comparison of adsorption energies between the MoS₂-NT and MoS₂-monolayer (ML)⁷ which clearly indicates that the MoS₂-NT shows greater adsorption energies compared to MoS₂-ML (adsorption energies are given in Table S2, ESI†).

From the above figure, it is clear that the nucleophilic gases NH₃ and H₂O are adsorbed more strongly on the (6,6) MoS₂-NT yielding higher adsorption energies, while the electrophilic gases CO and CO₂ are less strongly adsorbed with lower adsorption energies. Analysis of bond lengths and adsorption energies revealed that the nucleophilic gases are adsorbed preferentially over the electrophilic sites on the (6,6) MoS₂-NT, while electrophilic gases prefer to bind to the nucleophilic sites more. The bond distances of CO and CO₂ from their nearest sulphur atom of the MoS₂-NT are 2.95 Å and 2.82 Å, respectively, while the bond distances of NH₃ and H₂O from their nearest Mo atom are 2.32 Å and 2.20 Å, respectively. Higher values of adsorption energies of the nucleophilic gases are also understood from the Mulliken charge analysis. Fig. 3 enlists the Mulliken charges of the composite systems studied (data are listed in Table S3, ESI†).

It was found that, for NH₃ and H₂O, 0.25 and 0.08 electronic charges were respectively transferred to the MoS₂-NT on adsorption. However, 0.08 and 0.07 electronic charges were transferred from the MoS₂-NT to the anti-bonding π^* -orbital of CO and CO₂ gases, respectively. The charge transfer from the MoS₂-NT to CO and CO₂ is further understood from the elongation of the C–O bond from 1.14 Å to 1.15 Å in CO and from 1.17 Å to 1.28 Å in CO₂ as these gases are adsorbed on the MoS₂-NT. Similarly, the charge transfer from MoS₂ to NH₃ and H₂O is further evident from the elongation of the N–H bond from 1.02 Å to 1.03 Å in NH₃ and of the O–H bond from 0.97 Å to 1.02 Å in H₂O along with the change in the bond angle in both NH₃ and H₂O molecules, as these are adsorbed on the MoS₂-NT.

The valence band maxima (VBM) and conduction band minima (CBM) of the composite systems are in accordance with the Mulliken charge analysis. Fig. 4 shows how the electrophilic

Fig. 3 Mulliken charges on gases adsorbed on the MoS₂-NT.

Fig. 4 Charge density isosurface (isoval = 0.02) plot for MoS₂-NT@gases: (a) MoS₂-NT-CO, (b) MoS₂-NT-CO₂, (c) MoS₂-NT-NH₃, and (d) MoS₂-NT-H₂O.

and nucleophilic character of the gases affect the charge transfer from the MoS₂-NT to gases and *vice versa*. The charge density distribution shown in Fig. 4 clearly demonstrates that a substantial amount of electron density is transferred from the NT to electrophilic CO and CO₂ while for NH₃ and H₂O a reverse trend is observed.

Structural parameters of these gases before and after adsorption are presented in Table 1. The obtained results revealed a significant change in the structure of the gases after adsorption on the (6,6) MoS₂-NT. Bond lengths of all gases are increased upon adsorption on the NT. Bond angles are also increased in CO₂, NH₃ and H₂O after adsorption. For CO and CO₂, the bond lengths are increased by 0.01 Å and 0.11 Å, respectively, along with a change in the bond angle from 179.94° to 119.32° in the case of CO₂. In the case of NH₃ and H₂O, the bond lengths are increased by 0.01 Å and 0.05 Å, respectively, and the bond angles are increased by 2.40° and 0.75° , respectively, after adsorption.

The projected density of states (PDOS) of different gases adsorbed on the MoS₂-NT is plotted in Fig. 5a–e to analyse the contribution arising from the gases and the MoS₂-NT to the corresponding valence and conduction bands of the composite systems. It must be noted that the more electronegative S atom appears in the valence band while the more electropositive Mo atom contributes to the conduction band of the MoS₂-NT. Furthermore, compared to the free MoS₂-NT, the composite

Table 1 Structural changes of gases after adsorption on the MoS₂-NT

Gas	Bond length in free gas (Å)	Bond angle in free gas (degree)	Bond length in adsorbed gas (Å)	Bond angle in adsorbed gas (degree)
CO	1.14	—	1.15	—
CO ₂	1.17	179.94	1.28	119.32
NH ₃	1.02	107.49	1.03	109.89
H ₂ O	0.97	104.89	1.02	105.64

systems showed smaller band gaps. The nucleophilic NH₃ and H₂O gases appear in the corresponding conduction band of the composite system due to the transfer of electron density from the gases to the conduction band of the MoS₂-NT. With electrophilic gases, there is a significant charge transfer from the more electronegative sulphur of the MoS₂-NT to the corresponding vacant orbital of the CO and CO₂ gases, resulting in the elongation of the C–O bond (bond length 1.14 to 1.15 Å) in CO while a change in hybridization from sp to sp² in CO₂.

To analyze the performance of the MoS₂-NT as a potential sensor, the non-equilibrium Green's function (NEGF) method is employed to evaluate the transport and corresponding current–voltage (*I*–*V*) characteristics of the MoS₂-NT before and after gas adsorption. The model systems of the designed two semi-infinite electrodes along with the scattering region where the different gases were adsorbed are shown in Fig. 6.

A remarkable effect of gas adsorption on current–voltage characteristics is observed from the *I* vs. *V* curve as presented in

Fig. 7. For all gas adsorption cases, *I* vs. *V* showed a noticeable increase in current flow with respect to the pristine MoS₂-NT. This increase in the current signal clearly indicates that there is a huge impact on the transport characteristics of the MoS₂-NT after gas adsorption. Among the four different gas adsorption cases, the CO₂ adsorbed MoS₂-NT showed enhanced current flow. However NH₃ and CO adsorbed MoS₂-NTs showed almost a similar current flow, and the H₂O adsorbed MoS₂-NT showed the least current flow. A similar effect of NH₃ and CO adsorbed MoS₂-NTs can be attributed to the similarity of the energy difference between the conduction and valence bands. On the other hand, the stronger effect of CO₂ adsorption on the transport characteristics can be explained from the large decrease of the CBM and VBM energy states. It is interesting to note that, though H₂O is strongly adsorbed on the MoS₂-NT (−1.74 eV) and there is a large decrease in the CBM and VBM levels, current flow is least affected by H₂O adsorption. Such current–voltage behaviour for H₂O and CO₂ adsorption can be

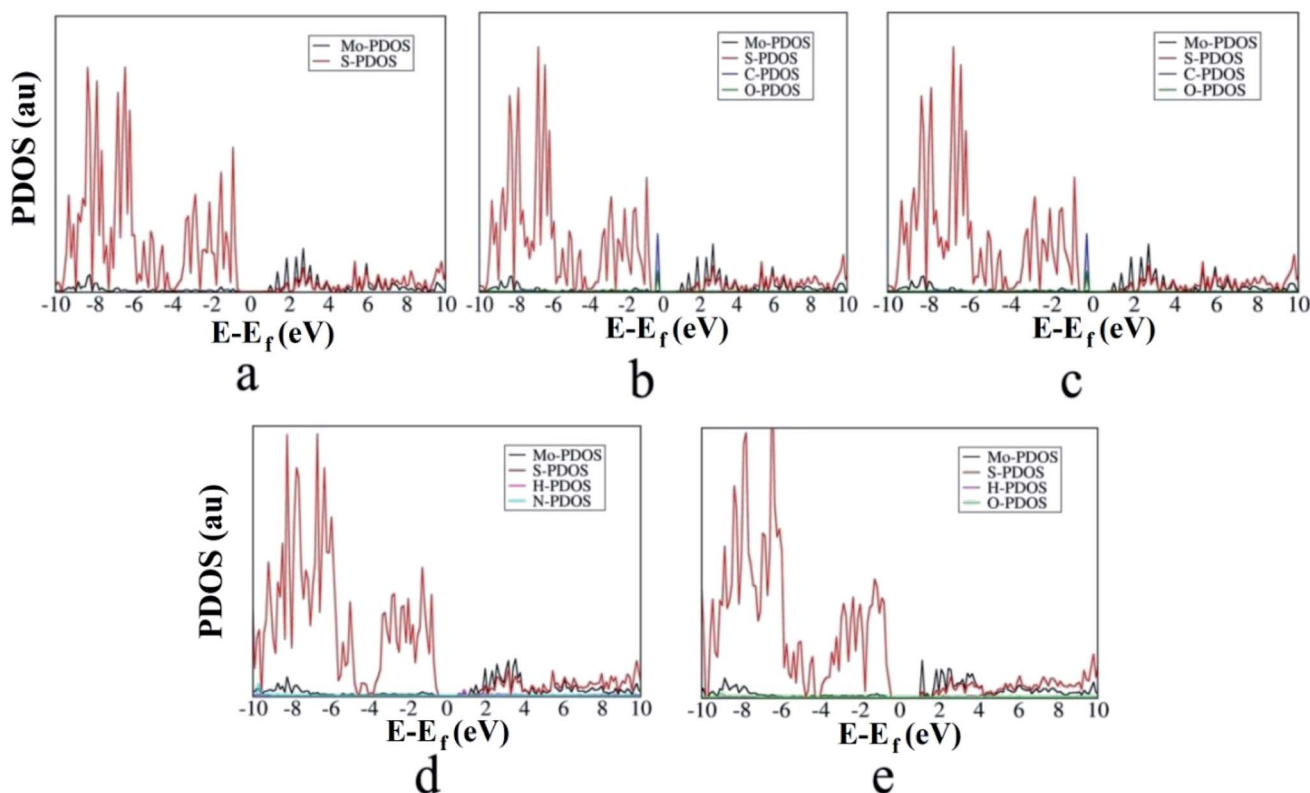

Fig. 5 PDOS of the (6,6) MoS₂-NT and MoS₂-NT@gases: (a) MoS₂-NT, (b) MoS₂-NT@CO, (c) MoS₂-NT@CO₂, (d) MoS₂-NT@NH₃ and (e) MoS₂-NT@H₂O.

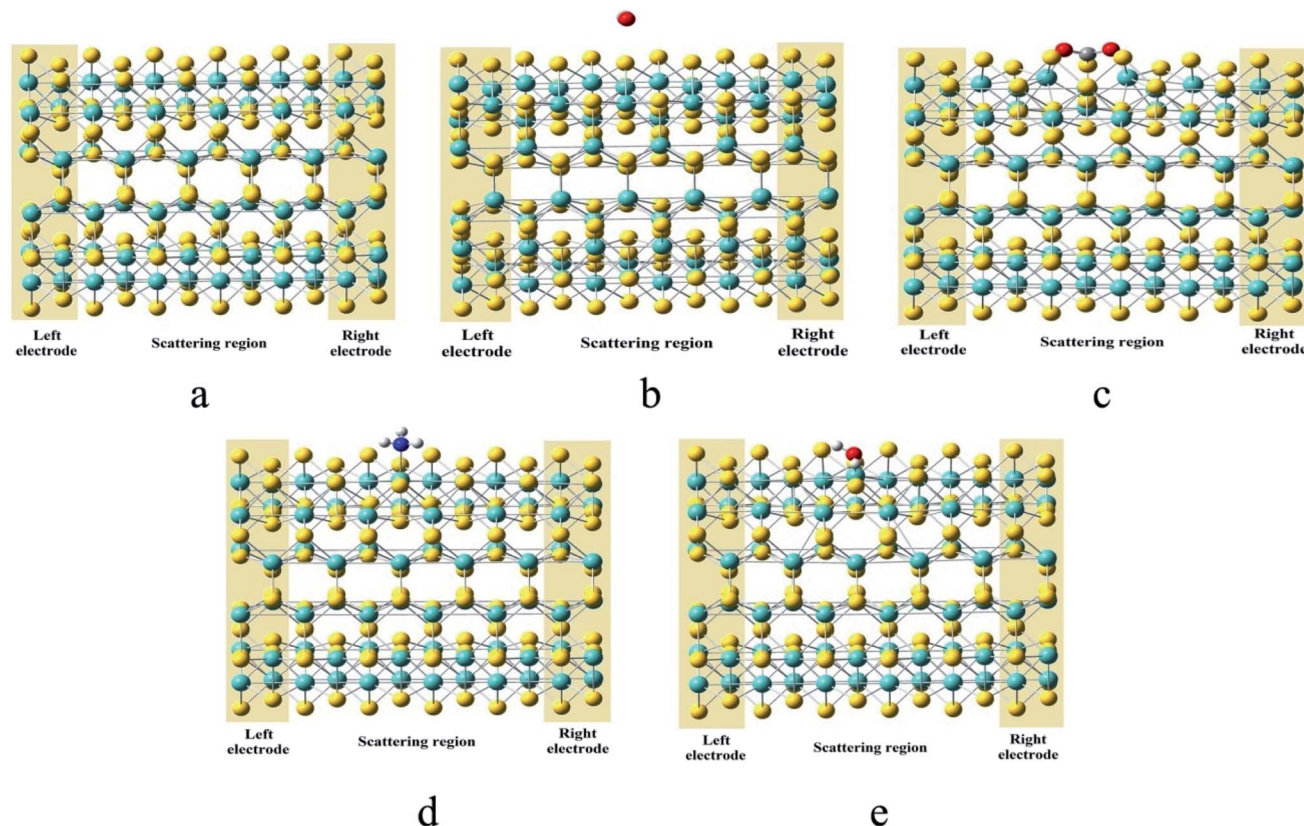

Fig. 6 Optimised geometries of (a) the $\text{MoS}_2\text{-NT}$, (b) $\text{MoS}_2\text{-NT@CO}$, (c) $\text{MoS}_2\text{-NT@CO}_2$, (d) $\text{MoS}_2\text{-NT@NH}_3$, and (e) $\text{MoS}_2\text{-NT@H}_2\text{O}$ with electrodes and the scattering region.

interpreted by the inhibition of the conduction channel due to an appreciable amount of charge flow from H_2O to the $\text{MoS}_2\text{-NT}$.

The noticeable difference in the current signal due to gas adsorption can be regarded as a superior characteristic of the device modelling of $\text{MoS}_2\text{-NT}$ based gas sensors.

To better understand the shifting of conduction and valence bands due to charge transfer after adsorption of gases, we have

plotted the transmission function for bare and adsorbed NTs as shown in Fig. 8. Charge transfer in $\text{MoS}_2\text{-NT@CO}_2$ from the $\text{MoS}_2\text{-NT}$ to CO_2 results in the shrinking of the transport bands and the transmission function shows a broad peak in conduction and valence bands. As a result, CO_2 adsorption increases the conduction channel in $\text{MoS}_2\text{-NT@CO}_2$, showing a broad current signal in the I vs. V window. On the other hand, charge transfer from H_2O to the $\text{MoS}_2\text{-NT}$ shifts the conduction band to a lower energy, thereby inhibiting the conduction channel which shows lower transmission peaks. A similar behaviour in the current signal in the I vs. V window for $\text{MoS}_2\text{-NT@NH}_3$ and $\text{MoS}_2\text{-NT@CO}$ has been attributed to the alignment of similar transport bands and transmission signals in valence and conduction bands.

Furthermore, to understand how adsorption affects the overall band structure of these systems, we have performed band structure analysis of the $\text{MoS}_2\text{-NT}$ and gas adsorbed $\text{MoS}_2\text{-NT}$ as shown in Fig. 9a–e. Fig. 9a revealed an indirect band gap of 0.19 eV for the free $\text{MoS}_2\text{-NT}$. After gas adsorption, there is a profound impact on the band structure of the system.

After adsorption of different gases, the indirect band gap decreases in all cases. For $\text{MoS}_2\text{-NT@CO}$, the band gap is 0.13 eV and for $\text{MoS}_2\text{-NT@CO}_2$, this band gap is reduced further to 0.04 eV. Again, in $\text{MoS}_2\text{-NT@NH}_3$, the band gap is 0.15 eV and for $\text{MoS}_2\text{-NT@H}_2\text{O}$, there is an overlap between the valence and conduction bands. For $\text{MoS}_2\text{-NT@CO}$ and $\text{MoS}_2\text{-NT@CO}_2$, the conduction bands become more dense compared to those of

Fig. 7 I vs. V characteristics of the $\text{MoS}_2\text{-NT}$, $\text{MoS}_2\text{-NT@CO}$, $\text{MoS}_2\text{-NT@CO}_2$, $\text{MoS}_2\text{-NT@NH}_3$ and $\text{MoS}_2\text{-NT@H}_2\text{O}$.

Fig. 8 Transmission function of (a) the MoS₂-NT, (b) MoS₂-NT@CO, (c) MoS₂-NT@CO₂, (d) MoS₂-NT@NH₃, (e) MoS₂-NT@H₂O and PDOS of (f) the MoS₂-NT, (g) MoS₂-NT@CO, (h) MoS₂-NT@CO₂, (i) MoS₂-NT@NH₃, (j) MoS₂-NT@H₂O.

MoS₂-NT. Furthermore, in the case of MoS₂-NT@NH₃ and MoS₂-NT@H₂O, the density of the conduction band is increased further. Hence the band structure is also in concordance with the Mulliken charge analysis and VBM-CBM analysis. Only in the case of MoS₂-NT@H₂O, the conduction band crosses the Fermi level, which is an indication of the metallic character of the system. It is also clear from the band structure that the MoS₂-NT shows much stronger binding with H₂O. Thus the

Fig. 9 Band structure of the MoS₂-NT and MoS₂-NT@gases: (a) MoS₂-NT, (b) MoS₂-NT@CO, (c) MoS₂-NT@CO₂, (d) MoS₂-NT@NH₃ and (e) MoS₂-NT@H₂O.

band structures also explain the binding nature of the gases on the MoS₂-NT.

Conclusions

In the present work, the adsorption of environmentally hazardous gases on the (6,6)-MoS₂-NT was analysed from their electronic structure and transport properties. Binding is controlled by the electrophilic and nucleophilic characters of the gases, which also govern charge transfer to and from the MoS₂-NT. The electrophilic character of CO and CO₂ lead to charge transfer from the NT to these gases, whereas the nucleophilic character of NH₃ and H₂O showed the reverse trend. These gases, upon adsorption on the MoS₂-NT, are activated, as evident from the structural changes in these gases. These phenomena are explained by Mulliken charge analysis, VBM-CBM analysis, *I* vs. *V* characteristics, transmission function, PDOS and band structure analysis. The presence of more electronegative atoms on the molecule also controls the binding energy and the band structure of the systems studied. Analysis of data reveals that compared to MoS₂-ML, the MoS₂-NT showed enhanced gas sensing ability and distinct *I*-*V* characteristics, which suggests the fabrication of new gas sensing devices from the MoS₂ based NT.
