# Host–guest modes and supramolecular frameworks of complexes of tetramethyl cucurbit[6]uril with 4-chloroaniline and 4,4'-diaminostilbene†

Ye Meng, Weiwei Zhao, Jun Zheng, Daofa Jiang, Jie Gao, Yanmei Jin and Peihua Ma \*

Since the first report on decamethylcucurbit[5]uril (Me<sub>10</sub>Q[5]) in 1992, substituted cucurbit[*n*]urils have attracted considerable research interest. In this study, the host–guest modes between the tetramethyl cucurbit[6]uril (TMeQ[6]) as a host and 4-chloroaniline and 4,4'-diaminostilbene (**G1** and **G2**) as guests were investigated by single-crystal X-ray diffraction, NMR, ITC, UV-Vis spectrum, and MALDI-TOF mass spectrometry analyses. The experimental results showed that TMeQ[6] formed a 1 : 1 inclusion compound with **G1**, and the carbonyl portal of TMeQ[6] formed a 1 : 1 self-assembly with **G2**. Further, multi-dimensional supramolecular frameworks were formed driven by weak interaction forces in the system (hydrogen bonding, C–H⋯π interactions, ion–dipole interactions, and dipole–dipole interactions).

## 1. Introduction

Various porous materials, namely, inorganic porous materials<sup>1,2</sup> (such as molecular sieves), organic–inorganic hybrid porous materials<sup>3–5</sup> (such as metal–organic frameworks, MOFs), and porous organic framework (POF) materials<sup>6,7</sup> have been developed. These porous materials have been widely used in adsorption, heterogeneous catalysis, and ion exchange processes.<sup>8–10</sup> Interestingly, in recent years, the use of weak forces as the driving force to construct supramolecular frameworks has been explored,<sup>11,12</sup> so the selection of suitable construction units has also become crucial. Cucurbit[*n*]uril is a fourth-generation supramolecular macrocyclic compound after crown ether, cyclodextrin, and calixarene; there are two main types: ordinary cucurbit[*n*]urils<sup>13–18</sup> and modified cucurbit[*n*]urils (decamethylcucurbit[5]uril, cyclopentyl-modified cucurbit[*n*]urils and so on).<sup>19–24</sup> Their structure has a hydrophobic cavity, two carbonyl portals, and an outer surface. The charge distribution in cucurbit[*n*]uril itself is not uniform, which makes cucurbit[*n*]uril a permanent dipole<sup>25</sup> (the cavity of the cucurbit[*n*]uril has an electrically neutral potential, the outer surface has a positive potential, and the carbonyl portal shows a negative potential). This is conducive to the study of the host–guest chemistry<sup>26–30</sup> and coordination chemistry<sup>31–35</sup> of the

cucurbit[*n*]uril, and to the construction of good reversible supramolecular organic frameworks<sup>36,37</sup> (SOFs).

Based on A–H⋯B (A and B are oxygen, nitrogen or fluorine) hydrogen bond theory.<sup>38</sup> There was ion–dipole interaction between [ZnCl<sub>4</sub>]<sup>2–</sup> and [CdCl<sub>4</sub>]<sup>2–</sup> anions and positive potential outer surface of cucurbit[*n*]urils, which makes them conducive to the construction of self-assembly complexes based on cucurbit[*n*]uril, so considered to be known to function as effective structure directing agents.<sup>39</sup> In this work, [ZnCl<sub>4</sub>]<sup>2–</sup> (formed from ZnCl<sub>2</sub> in an aqueous HCl solution) was used as structure directing agents, TMeQ[6]-based SOFs, namely, C<sub>92</sub>H<sub>110</sub>Cl<sub>17</sub>N<sub>50</sub>O<sub>28</sub>Zn<sub>4</sub> (**1**) and C<sub>68</sub>H<sub>76</sub>Cl<sub>8</sub>N<sub>28</sub>O<sub>12</sub>Zn<sub>2</sub> (**2**) were constructed by the supramolecular collaborative assembly. The driving force of complexes **1** and **2** was studied through single-crystal X-ray diffraction analysis, and the host–guest interaction between TMeQ[6] and guest molecules was studied through NMR, ITC, UV-Vis spectrum and MALDI-TOF mass spectrometry analyses. The experimental results showed that TMeQ[6]-based host–guest SOFs are promising for several applications, *e.g.*, in selective adsorption, heterogeneous catalysis, and ion exchange (Scheme 1).

## 2. Experimental

### 2.1 Experimental reagents

All the reagents were purchased from Aladdin Industrial Corporation (AR, Shanghai, China). TMeQ[6] was synthesized according to the method reported in a previous paper.<sup>40</sup>

### 2.2 Synthesis of the complexes

TMeQ[6] (10 mg, 9.51 μmol) and **G1** (2.55 mg, 20 μmol) were placed in a crystal bottle and 3 mol L<sup>–1</sup> hydrochloric acid (5 mL) was added;

Key Laboratory of Macrocyclic and Supramolecular Chemistry of Guizhou Province, Guizhou University, Guiyang 550025, People's Republic of China. E-mail: phma@gzu.edu.cn

† Electronic supplementary information (ESI) available. CCDC 2039065 (**1**) and 2039066 (**2**). For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/d0ra09074c

Scheme 1 TMeQ[6] and guest molecules used in this study.

the mixture was heated until dissolution. Then, a small amount of the inducing agent  $\text{ZnCl}_2$  was added, and the solution was heated and stirred for 5–10 min in a water bath at 35 °C. Finally, the solution was allowed to stand at room temperature for 7–10 days to obtain single crystals of complex **1** (35% yield). Complex **2** was synthesized (28% yield) in the same manner as complex **1**.

### 2.3 Crystal structure determination

A crystal with the appropriate size and transparency was selected and fixed on a glass probe with petroleum jelly. A Bruker Smart Apex II single-crystal X-ray diffractometer, with Mo- $K_\alpha$  radiation ( $\lambda = 0.071073$  nm), was used for the characterization. The SHELX-97 (ref. 41) program packages were used for data refinement by the full-matrix least-squares method, and the SQUEEZE routine of the PLATON program was used to process solvent molecules in the crystal. The X-ray crystallographic data for structures reported in this study have been deposited in the Cambridge Crystallographic Data Center under accession numbers CCDC: 2039065 (**1**) and 2039066 (**2**).† The crystal parameters, data acquisition conditions, and parameters of the complexes **1** and **2** are listed in Table 1.

### 2.4 Determination by <sup>1</sup>H NMR

**G1**, **G2**, and TMeQ[6] were each dissolved in neutral D<sub>2</sub>O. The guest solution concentration was fixed at 0.1 mM in all analyses. The TMeQ[6] solution was added dropwise until it was in excess of the guest solution, and the <sup>1</sup>H NMR spectra were recorded at appropriate intervals using a JEOL JNM-ECZ400s spectrometer at 25 °C. D<sub>2</sub>O was used as a field-frequency lock, and the observed chemical shifts are reported in parts per million (ppm) relative to D<sub>2</sub>O as an internal standard ( $\delta = 4.67$  ppm).

### 2.5 Determination by isothermal titration calorimetry

The neutral aqueous solution of TMeQ[6] ( $1.0 \times 10^{-4}$  mol L<sup>−1</sup>, 1.00 mL) was placed in the sample cell, and a  $1.00 \times 10^{-3}$  mol L<sup>−1</sup> **G1** solution was drawn into a 250 mL syringe. The temperature was set at 25 °C, and the titration was conducted by adding 30 aliquots (8 μL) of the **G1** solution at intervals of 300 s. The same method was used for TMeQ[6] and **G2**. The thermodynamic parameters of each system were determined on a nano ITC isothermal calorimeter. After deleting the first one unwanted data points, the data were analyzed with Launch NanoAnalyze software using an independent model.

### 2.6 Determination by UV-Vis spectrum

The neutral aqueous solution of TMeQ[6] ( $1.0 \times 10^{-4}$  mol L<sup>−1</sup>) and **G1** ( $1.0 \times 10^{-3}$  mol L<sup>−1</sup>) were prepared as stock solutions, and the UV-Vis absorption spectrum of each substance was measured by the molar ratio. Add 300 μL of **G1** stock solution to eleven 10 mL volumetric bottles, then add corresponding volume of TMeQ[6] stock solution to these volumetric bottles, and maintain molar ratios of 0, 0.2, 0.4, 0.6, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8 and 2.0 after volume determination with doubly-distilled water. The measurements were performed at room temperature with an UV-2700 external spectrometer. The same method was used for TMeQ[6] and **G2**.

### 2.7 Determination by mass spectrometry

The neutral aqueous solution of TMeQ[6] ( $1.0 \times 10^{-4}$  mol L<sup>−1</sup>) was prepared, and 1 mL was pipetted into a centrifuge tube. Then, 100 μL of the **G1** aqueous solution with a concentration of  $1 \times 10^{-3}$  mol L<sup>−1</sup> was added. The solution was filtered into a chromatographic sample bottle using aqueous 0.22 μm syringe filters. Mass spectra were recorded on an Agilent 6545 Q-TOF mass spectrometer. The same method was used for TMeQ[6] and **G2**.

## 3. Results and discussion

### 3.1 Description of the crystal structures of complexes **1** and **2**

**3.1.1 Description of the crystal structure of complex **1**.** Complex **1** exhibits the triclinic  $P\bar{1}$  space group. As shown in Fig. 1a, TMeQ[6] and protonated 4-chloroaniline formed a 1 : 1 inclusion compound. In this system, hydrogen bonds are one of the main forces. N49 forms three hydrogen bonds with O2, O4, and O6, and N50 forms three hydrogen bonds with O16, O18, and O20; the N–H...O hydrogen bond length is 2.760–2.834 Å. In addition, hydrogen bonds form between O1 and O2 and

Fig. 1 Structure of complex 1: (a) 1 : 1 inclusion compound of TMeQ[6] and G1, (b) hydrogen bond interaction, (c) ion–dipole interaction, and (d) dipole–dipole interaction.

between O15 and O16 (O2–H2A...O1 and O16–H16A...O15), with the bond lengths being 2.859 and 2.855 Å, respectively (Fig. 1b). One counterion  $[\text{ZnCl}_4]^{2-}$  connects with three adjacent outer surfaces of TMeQ[6]s *via* ion–dipole interactions (Fig. 1c). A negatively potential TMeQ[6] portal is connected to another positively potential outer surface of TMeQ[6] by the dipole–dipole interaction (Fig. 1d). In summary, these weak interactions

Fig. 2 Supramolecular framework of complex 1: (a) two-dimensional framework structure viewed along the *b*-axis, (b and c) three-dimensional supramolecular framework structure viewed along *b*-axis and *c*-axis, respectively, and (d) three-dimensional layered framework.

(hydrogen bonding, ion–dipole interaction, and dipole–dipole interaction) caused complex 1 to form an ordered multi-dimensional layered supramolecular framework (Fig. 2a–d).

### 3.1.2 Description of the crystal structure of complex 2.

Complex 2 exhibits the triclinic  $P\bar{1}$  space group. The asymmetric unit contains half of TMeQ[6], one counterion  $[\text{ZnCl}_4]^{2-}$ , and two half of protonated 4,4'-diaminostilbenes, as shown in Fig. 3a. Counterions  $[\text{ZnCl}_4]^{2-}$  connects with adjacent TMeQ[6]s by ion–dipole interactions (Fig. 3b). In fact, protonated 4,4'-diaminostilbene also connects with the methylene hydrogen (–CH) and bridging “waist” methylene (–CH<sub>2</sub>) of TMeQ[6]s by C–H... $\pi$  interactions (Fig. 3c). Further, TMeQ[6] and protonated 4,4'-diaminostilbene form a 1 : 1 assembly *via* hydrogen bonds, where N1 of protonated 4,4'-diaminostilbene forms two hydrogen bonds with O1 and O2 of TMeQ[6], and N14 of protonated 4,4'-diaminostilbene forms a hydrogen bond with Cl2 of counterions  $[\text{ZnCl}_4]^{2-}$ . These hydrogen bonds—*i.e.*, N1–H1A...O1, N1–H1B...O2, and N14–H14A...Cl2—have bond lengths of 2.789, 2.734, and 3.277 Å, respectively (Fig. 3d). Hydrogen bonding, C–H... $\pi$ , and ion–dipole interactions were the driving forces in the construction of the supramolecular assembly. As shown in Fig. 3e, the extension of supramolecular assembly at different angles can result in different shapes. By taking the angle of view along the *b*-axis as an example and by only considering the hydrogen bond between the portal of TMeQ[6] and 4,4'-diaminostilbene, a one-dimensional supramolecular chain is formed (Fig. 4a). Interestingly, when multiple forces coexist, 4,4'-diaminostilbene forms a “walled” supramolecular framework enclosing TMeQ[6]s, eventually forming the two-dimensional supramolecular framework (Fig. 4b) and the three-dimensional framework (Fig. 4c).

Fig. 3 Structure of complex 2: (a) asymmetric unit, (b) ion–dipole interaction, (c) C–H... $\pi$  interaction, (d) hydrogen bond interaction, and (e) assembly of unit cell.

### 3.2 $^1\text{H}$ NMR, ITC, UV-Vis spectrum, and MALDI-TOF mass spectrometric analysis of cucurbiturils and guests

**3.2.1  $^1\text{H}$  NMR spectra of TMeQ[6] and guests.** The cavity of TMeQ[6] has a shielding effect on proton signals, whereas outside of the portals, in the vicinity of the carbonyl oxygen atoms, the proton signals are subjected to a deshielding effect. Therefore, nuclear magnetic resonance (NMR) is one of the most commonly used techniques to investigate host-guest interactions. Fig. 5 and 6 show the  $^1\text{H}$  NMR results of interactions of G1 and G2 with TMeQ[6] in  $\text{D}_2\text{O}$ , respectively.

Fig. 5a shows the  $^1\text{H}$  NMR spectrum of G1; Fig. 5b, c, and d show the  $^1\text{H}$  NMR spectra of TMeQ[6]–G1 with an equivalent ratio of 0.51, 1.08, and 1.36, respectively; and Fig. 5e shows the

Fig. 5 Titration  $^1\text{H}$  NMR spectra of G1 (0.1 mM) with (a) 0.00, (b) 0.51, (c) 1.08, and (d) 1.36 equiv. of TMeQ[6], and of (e) neat TMeQ[6].

Fig. 6 Titration  $^1\text{H}$  NMR spectra of G2 (0.1 mM) with (a) 0.00, (b) 0.71, and (c) 1.39 equiv. of TMeQ[6], and of (d) neat TMeQ[6].

$^1\text{H}$  NMR spectrum of TMeQ[6]. When TMeQ[6] was added to the system, the chemical shift of  $\text{H}_\alpha$  and  $\text{H}_\beta$  protons of G1 moved upfield by about  $\delta$  0.175 and 0.449 ppm, respectively. This indicates that G1 penetrated into the cavity of TMeQ[6] and was shielded by TMeQ[6]. Moreover, when TMeQ[6] was greater than 1 equiv., the chemical shift of protons  $\text{H}_\alpha$  and  $\text{H}_\beta$  remained unchanged, indicating that TMeQ[6] and G1 formed a 1 : 1 inclusion compound, and the existence of the amino group and Cl atom in G1 resulted in the splitting of proton peaks of TMeQ[6].

Further, Fig. 6a shows the  $^1\text{H}$  NMR spectrum of G2; Fig. 6b and c show the  $^1\text{H}$  NMR spectra of TMeQ[6]–G2 with an equivalent ratio of 0.71 and 1.39, respectively; and Fig. 6d shows the  $^1\text{H}$  NMR spectrum of TMeQ[6]. When TMeQ[6] was added to the system, the chemical shifts of the protons  $\text{H}_\alpha$ ,  $\text{H}_\beta$ , and  $\text{H}_\gamma$  of the guest G2 moved downfield, indicating that G2 was at the portal of TMeQ[6] and was subject to the deshielding effect of TMeQ[6]. The proton peaks of TMeQ[6] did not split, indicating that the protons of TMeQ[6] were in a symmetrical environment. By comparing Fig. 6b and c, when the amount of TMeQ[6] increased, the protons  $\text{H}_\alpha$ ,  $\text{H}_\beta$  and  $\text{H}_\gamma$  of the guest G2 moved up to the downfield, indicating that TMeQ[6] and G2 was an unstable reversible dynamic interaction.<sup>42</sup>

**3.2.2 Isothermal titration calorimetry.** Isothermal titration calorimetry (ITC) experiments (Fig. 7) were performed to determine the thermodynamic parameters of the above two guests and TMeQ[6] in water, providing insight into the thermal

Fig. 7 Titration diagram of isothermal titration calorimetry: (a) TMeQ[6]@G1, (b) TMeQ[6]@G2.

**Table 2** Thermodynamic parameters of the interactions of TMeQ[6] with G1 and G2

Experiment	$K_a$ ( $M^{-1}$ )	$\Delta H$ ( $kJ\ mol^{-1}$ )	$T\Delta S$ ( $kJ\ mol^{-1}$ )	$\Delta G$
G1·TMeQ[6]	$1.484 \times 10^5$	−80.89	−51.37	−29.52
G2·TMeQ[6]	$5.194 \times 10^3$	−100.00	−78.79	−21.21

stability and driving force of the interactions. The enthalpies and entropies of the interactions of the two guests and TMeQ[6] are both negative (Table 2). From the contributions of these two thermodynamic parameters to the Gibbs free energy ( $\Delta G = -RT \ln K_a = \Delta H - T\Delta S$ ), it can be seen that the two systems are enthalpy-driven, and the driving force is determined by the hydrogen bond interaction and the hydrophobic effect. By comparing the binding constants of G1·TMeQ[6] and G2·TMeQ[6], the stability of G1 entering the cavity of TMeQ[6] is greater than that of G2 at the portals of TMeQ[6]. G2·TMeQ[6] has a weak binding affinity, resulting in a reversible dynamic interaction of G2·TMeQ[6] (Table 2).

**3.2.3 UV-Vis spectrum analysis.** The binding behaviors of TMeQ[6]@G1 and TMeQ[6]@G2 were studied by employing UV-Vis absorption in deionized water (Fig. 8). The wavelengths of the one strong absorption peak for G1 was observed at 238 nm, and TMeQ[6] exhibited no absorption at these wavelengths. The absorbance of G1 shows a gradually downward trend upon increasing the ratio of  $n(\text{TMeQ[6]})/n(\text{G1})$ . When the ratio of  $n(\text{TMeQ[6]})/n(\text{G1})$  reaches 1, the absorbance becomes stable as the ratio increases. Therefore, the absorbance (A) vs. the molar ratio of the TMeQ[6] and G1  $\{n(\text{TMeQ[6]})/n(\text{G1})\}$  data can be fitted to a 1 : 1 binding (Fig. 8a). In addition, the wavelengths of the one strong absorption peak for G2 was observed at 306 nm, and TMeQ[6] exhibited no absorption at these wavelengths. The absorbance of G2 shows a gradually downward trend upon increasing the ratio of  $n(\text{TMeQ[6]})/n(\text{G2})$ . According to the tangent intersection, the absorbance (A) vs. the molar ratio of the TMeQ[6] and G2  $\{n(\text{TMeQ[6]})/n(\text{G2})\}$  data can be fitted to a 1 : 1 binding (Fig. 8b).

**3.2.4 Mass spectrometry.** In order to further investigate the host–guest interaction modes, as shown in Fig. 9, matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry was used to characterize the complex structures. The molecular ion peaks are visible at  $m/z$  1180.3840 and 1263.4626, and these could correspond to  $[\text{TMeQ[6]} + \text{G1} + \text{H}]^+$  and  $[\text{TMeQ[6]} + \text{G2} + \text{H}]^+$ , respectively (calculated  $m/z$  values

**Fig. 9** Mass spectrometry of (a) TMeQ[6]@G1, and (b) TMeQ[6]@G2.

were 1180.3832 and 1263.4811, respectively). Therefore, TMeQ[6] and guests interacted at a ratio of 1 : 1, which is consistent with the above analysis results.

## 4. Conclusions

In this study, the interaction modes of TMeQ[6] with G1 and G2 were investigated by performing single-crystal X-ray diffraction, NMR, ITC, UV-Vis spectrum, and MALDI-TOF mass spectrometry analyses. The experimental results showed that TMeQ[6] and G1 formed a 1 : 1 inclusion complex, and the carbonyl portal of TMeQ[6] formed a 1 : 1 self-assembly with G2. The single crystal structures of complexes 1 and 2 exhibited the ion–dipole interaction, dipole–dipole interaction, C–H... $\pi$  interaction, and hydrogen bonds. These weak interaction forces caused complexes 1 and 2 to form ordered multi-dimensional supramolecular frameworks. They are expected to have a wide range of applications in nanotechnology, molecular sieves, sensors, gas adsorption and separation, ion or molecular transportal, and heterogeneous catalysis.
