Asymmetric addition of Grignard reagents to ketones: culmination of the ligand-mediated methodology allows modular construction of chiral tertiary alcohols†

Claudio Monasterolo,^{ID}* Ryan O'Gara, Saranna E. Kavanagh, Sadbh E. Byrne,^{ID} Bartosz Bieszczad, Orla Murray, Michael Wiesinger, Rebecca A. Lynch,^{ID} Kirill Nikitin^{ID} and Declan G. Gilheany^{ID}*

A new class of biaryl chiral ligands derived from 1,2-diaminocyclohexane (1,2-DACH) has been designed to enable the asymmetric addition of aliphatic and, for the first time, aromatic Grignard reagents to ketones for the preparation of highly enantioenriched tertiary alcohols (up to 95% ee). The newly developed ligands **L12** and **L12'** together with the previously reported **L0** and **L0'** define a set of complementary chiral promoters, which provides access to the modular construction of a broad range of structurally diverse non-racemic tertiary alcohols, bearing challenging quaternary stereocenters. The present advancements bring to completion our asymmetric Grignard methodology by expanding the scope to aromatic organomagnesium reagents, while facilitating its implementation in organic synthesis thanks to improved synthetic routes for the straightforward access to the chiral ligands. The synthetic utility of the method has been demonstrated by the development of a novel and highly enantioselective formal synthesis of the antihistamine API clemastine *via* intermediate (*R*)-**3a**. Exploiting the power of the 3-disconnection approach offered by the Grignard synthesis, (*R*)-**3a** is obtained in 94% ee with ligand (*R,R*)-**L12**. The work described herein marks the finalization of our ongoing effort towards the establishment of an effective and broadly applicable methodology for the asymmetric Grignard synthesis of chiral tertiary alcohols.

Introduction

Since Victor Grignard's early work at the beginning of the 20th century,¹ organomagnesium reagents have been established as an essential tool in organic chemistry, gaining a central role in a broad range of transformations and synthetic applications,² and remain the privileged subject of ongoing research interest today.³ Among the variety of applications offered by organomagnesium species,⁴ the asymmetric 1,2-addition of Grignard reagents to prochiral ketones has emerged as a powerful strategy providing access to non-racemic tertiary alcohols,⁵ widespread structural motifs and valuable synthetic intermediates for the preparation of complex chiral scaffolds, bioactive targets and APIs.⁶ Owing to the synthetic flexibility of the 3-disconnection approach, the Grignard synthesis enables the

straightforward and modular construction of molecular complexity from simple and cheap substrates (Scheme 1). However, the 1,2-addition of organomagnesium nucleophiles to ketones entails substantial challenges, due to the reduced reactivity of ketones and the presence of competing enolization pathways,⁷ which have posed a major limit to the development of effective synthetic methods to date. Recent reports successfully overcame these issues by modulating the reactivity of the Grignard reagent by the action of additional metal species,⁸ producing highly enantioenriched tertiary alcohols. Despite the excellent stereoselectivities achieved by the mixed-metals

strategies, the need for additional metal catalysts and additives affects the atom economy of the processes and limits the potential efficiency and sustainability offered by the Grignard approach. Consequently, the development of effective ligand-mediated, single metal based methods (*i.e.* requiring only a chiral ligand, without the need for additional metals and/or additives) is highly desirable, as it would give access to greener and more cost-effective methodologies featuring improved atom-economy and reduced waste production, in accordance with the modern green-chemistry requirements.

As a result of the challenges associated with asymmetric Grignard synthesis, only a few useable direct methods have been reported to date. The first example by Weber and Seebach in 1992,⁹ making use of TADDOL as chiral ligand, has been followed by the BINOL-mediated strategy developed by Osaka and Nakajima in 2016.¹⁰ Both methods suffered from drawbacks which limited their general implementation, such as the need for extremely low temperatures and limited scope. To overcome these limitations, we designed a conceptually new *N,N,O*-tridentate ligand **L0** derived from *trans*-1,2-diaminocyclohexane (1,2-DACH), which enabled the development of an effective ligand-mediated, single metal based approach to the asymmetric Grignard synthesis of chiral tertiary alcohols, *via* an operationally simple and cost-effective process (Scheme 2).¹¹ Fine tuning of **L0** led to the design of the *N*-pyrrole

analogue **L0'**¹² enhancing the stereoselectivity and broadening the scope to new classes of tertiary alcohols (Scheme 2a). The application of the asymmetric Grignard method to the synthesis of valuable targets provided new effective and step-economical entries to a range of challenging products, significantly shortening the previously established preparations, including: (i) natural products, *e.g.* tocopherols (vitamin-E) and tocotrienols¹³ and sesquiterpenes (gossonorol, boivinianin A and boivinianin B);¹⁴ (ii) chiral *O*-heterocycles (2,2-disubstituted THFs and THPs) and (iii) biologically active compounds, such as the anticonvulsant and hypnotic γ -ethyl- γ -phenyl butyrolactone and the antimalarial yingzhaosu C.^{10,12} Nevertheless, the efficient implementation of aromatic organomagnesium nucleophiles has remained elusive to date. This prompted us to undertake a comprehensive investigation of the ligand structure, with the aim to deepen our understanding of its impact over the stereoselectivity, and to address the compatibility issues hampering the use of aromatic Grignard reagents. Herein we report the development of a new class of biaryl ligands **L12** and **L12'** which, in addition to the previously established **L0** and **L0'**, complete our asymmetric Grignard methodology allowing the modular synthesis of a broad range of chiral tertiary alcohols. The new ligands enabled, for the first time, the effective implementation of aromatic organomagnesium nucleophiles, expanding the scope and synthetic utility of the strategy (Scheme 2b). The study is complemented by the development of new short, protection-free and purification-free synthetic routes for the preparation of the chiral ligands, to promote the straightforward implementation of the method in organic synthesis.

Results and discussion

At the onset of the study, we focused on the preparation of the new DACH-derived ligands to be screened **L1**–**L14**. First, we developed an improved one-pot synthetic route for the preparation of **L0**–**L3** from commercially available 1,2-DACH hydrochloride **4·HCl**.¹⁵ The new route was designed to provide an operationally simple and scaleable access to DACH-derived ligands, by means of a shorter and more cost-effective process, avoiding the need for *N*-protecting groups and the purification of intermediates. Reductive amination of **4·HCl** with substituted salicylaldehydes **5a–d**, followed by exhaustive Eschweiler–Clarke methylation of intermediates **6a–d**, efficiently delivered ligands **L0**–**L3** in two steps (Scheme 3, Route (a)), significantly shortening the previous four-step preparations.¹⁶ Next, we prepared the new biaryl ligands **L7**–**L14**. To get quick access to a range of *ortho*-aryl substituted analogues, a divergent route was designed involving the late-stage diversification of the common aryl bromide intermediate **L6** (Scheme 3, Route (b)).¹⁷ A convenient one-pot sequence was optimized to deliver halogenated intermediates **L4**–**L6** *via* reductive amination of *N*-Boc-1,2-DACH **7** with halogenated salicylaldehydes **5e–g** (X = F, Cl, Br), followed by deprotection and *N*-methylation, without the need for purification. Subsequent palladium-catalyzed cross-coupling of aryl bromide **L6** with different aryl boronic acids delivered the desired ligands **L7**–**L14**, obtained in

Unlike *ortho*-alkyl substituted **L1–L3** and *ortho*-halogenated **L4–L6** ligands, the introduction of a biaryl functionality in **L7–L14** enhanced the efficiency of the transformation, with the 3,5-bis(trifluoromethyl)phenyl substituted ligand (*R,R*)-**L12** resulting the most effective, delivering the desired tertiary alcohol (*S*)-**2a** in 87% ee (Table 1, entry 14). The high selectivity achieved by **L12** in the model reaction prompted us to further investigate the scope of the transformation. To our delight, the new ligand provided high to excellent enantioselectivities over a range of functionalized short-chain phenones (Table 2). With the aim to overcome the selectivity issues we previously observed in the addition of aryl Grignard reagents to ketones using ligand **L0**,¹⁸

the new ligands **L7–L14** were screened in the addition of *para*-chlorophenylmagnesium bromide to acetophenone **1a** (Table 3).¹⁹ While most of the new ligands failed to improve the enantioselectivity of the process (Table 3, entries 1–5 and 8), the use of (*R,R*)-**L12** showed unprecedented enantiocontrol, delivering the product (*R*)-**3a** in 89% ee (Table 3, entry 6). Taking into consideration the previously demonstrated positive effect

exerted by replacing the *N*-dimethyl group of ligand **L0** with *N*-pyrrole **L0'**,¹² we extended the investigation of (*R,R*)-**L12** to the *N*-pyrrole analogue (*R,R*)-**L12'** (Table 3, entry 7).²⁰ Thus, a range of substituted aryl Grignard reagents were reacted with functionalized phenones in the presence of (*R,R*)-**L12** and (*R,R*)-**L12'** (Table 4). Both ligands demonstrated a remarkable improvement in asymmetric induction compared to the modest level of stereocontrol of **L0** and **L0'**, providing access to diaryl-alkyl chiral tertiary alcohols **3a–m** in good to excellent enantioselectivities (Table 4). Complementary behaviors were observed in relation to the electronic demand of the aryl Grignard reagents and the nature of the functional groups present on the aromatic ring, as **L12** gave better results in the case of electron withdrawing groups, while **L12'** best performed in combination with electron donating substituents (Table 4).²¹

The new biaryl ligands **L12** and **L12'** for the first time enabled excellent asymmetric control over both alkyl and aryl Grignard nucleophiles, and thus allowed the implementation of the methodology in the preparation of novel classes of bioactive targets, as shown by the synthesis of the previously inaccessible highly enantioenriched alcohol (*R*)-**3a**, key intermediate in the synthesis of the antihistamine drug clemastine (Scheme 4).²² Following a comprehensive screening of conditions, addition of *para*-chlorophenylmagnesium bromide to acetophenone **1a**, in the presence of (*R,R*)-**L12**, delivered the product (*R*)-**3a** in 94% ee and 73% isolated yield (Scheme 4, Route (c)).²³ The newly developed highly enantioselective formal synthesis of clemastine further demonstrated the broad versatility and applicability of the methodology to the preparation of valuable APIs, and its compatibility with a wide range of structurally diverse ketone substrates and Grignard reagents.^{24,25}

Scheme 4 Modular access to highly enantioenriched (*R*)-**3a**, key intermediate in the synthesis of the antihistamine API clemastine.

Excited about the results delivered by the novel class of N,N,O-tridentate ligands derived from 1,2-DACH, from the early design of **L0** and the following structural variations to **L0'**, to the most recent development of the biaryl analogues **L12** and **L12'** presented herein, we were curious to identify the source of the enantioselectivity. At this point, we decided to step back and consider possible mononuclear and dinuclear hexacoordinated complexes involving the historical **L0**.¹¹ While the original rationale behind the design of the DACH tridentate ligands invoked the dinuclear model, the formation of highly active mononuclear ligand-magnesium species with the participation of electron-donating Lewis basic and anionic functionalities, *i.e.* N,N,O-tridentate ligand, halide, ethereal solvent and the carbonyl of the ketone substrate, was an alternative worth considering (Scheme 5).

In order to shed light on the nature of the chiral active species involved in the asymmetric Grignard reaction, the structure of the ligand-magnesium complex derived from **L0** and EtMgBr solution in Et₂O, was investigated. The X-ray crystallographic analysis of the material obtained by deprotonation of (*S,S*)-**L0** with EtMgBr, in toluene and in the absence of ketone, indicated the presence of an unexpected pseudo-mirror symmetrical trinuclear complex **C1** (molecular structure shown in Fig. 1, see ESI† for further details)²⁶ whereby the two hexacoordinated magnesium centres were bridged by bromide

Fig. 1 Molecular structure of the ligand-Mg complex **C1**, precipitated from toluene following deprotonation of (*S,S*)-**L0** with EtMgBr in Et₂O.

anions and featured the coordination with two separate deprotonated **L0** moieties. Careful examination of **C1** reveals that the stereochemical configurations of the benzylated chiral nitrogens N¹ of each **L0** ("key nitrogens"), are opposite in such a fashion that the hydroxylated aromatic groups on the two **L0** moieties have the same orientation, pointing "up" from the nominal plane of the DACH ring. Although the structure of complex **C1** crystallized from toluene may not be representative of the executive active species operating in solution, it clearly shows *fac*-coordination of the N,N,O-tridentate ligand **L0** to the hexacoordinated magnesium centre and the bridging halide, in good agreement with our original hypothesis.¹¹ The variability of the key nitrogen N¹ stereochemical configuration, however, points towards potential equilibration of multiple ligand-magnesium species in solution, owing to the molecular flexibility of the DACH-derived moieties. Indeed, ¹H-NMR analysis of the mixture resulting from the deprotonation of (*R,R*)-**L0** in toluene-*d*₈, *via* treatment with 1.0 equivalent of EtMgBr in Et₂O, clearly demonstrated the presence of multiple species deriving from **L0** in solution. The ¹H-¹H COSY correlations observed for the non-equivalent benzylic methylene protons (N¹-CH₂Ar), indicated the generation of at least five **L0**-derived species following deprotonation (see ESI† for details). Unfortunately, it was not possible to get further structural information due to extensive signal overlapping, further complicated by the presence of residual Et₂O deriving from the Grignard reagent solution.

These results suggested a substantially complex system being at play in the ligand-mediated asymmetric Grignard process, characterized by the concomitant presence of multiple potentially active ligand-magnesium species. On the basis of the findings provided by the X-ray and NMR analyses, we propose the establishment of an equilibrium in solution involving several stereoisomeric ligand-magnesium mononuclear complexes, along with possible dinuclear species. To this end, a further DFT computational study of mononuclear complexes **C2**, featuring magnesiated ligand (*R,R*)-**L0** and Et₂O solvent molecules, showed that the arrangement of the bromide anion opposite to the phenolic oxygen represents the energetically more stable orientation (Scheme 6). It also transpired that, among the two *trans*-species in equilibrium, *R*_(N1)-**C2** and *S*_(N1)-**C2**, the *S*_(N1) configuration of the key chiral nitrogen is more stable than the *R*_(N1) (*ca.* 2 kcal mol⁻¹ at the 6-31G* level, see ESI†), thus making complex *S*_(N1)-**C2** a potentially likely intermediate in the stereoselective process (Fig. 2).

Scheme 5 Proposed mononuclear ligand-Mg complex generated *via* deprotonation of (*R,R*)-**L0** with EtMgBr.

Scheme 6 Proposed equilibrium involving diastereomeric mono-nuclear ligand-Mg complexes C2, resulting from deprotonation of (*R,R*)-L0 with EtMgBr in Et₂O.

Fig. 2 DFT calculated molecular structures of *R*(N1)-C2 (a) and *S*(N1)-C2 (b).

The following step of the mechanism may involve coordination of the ketone substrate to the magnesium centre of C2 with replacement of one Et₂O molecule, leading to diastereomeric ligand-Mg-ketone intermediates whose stability is directly dictated by the sterics of the large *ortho-tert*-butyl functionality present in L0. Subsequent attack by external Grignard nucleophile, *via* asymmetric 1,2-addition to the Mg-coordinated ketone, would then produce the intermediate *tert*-alkoxide products in unequal stereochemical ratio. A more dedicated computational study of the mechanistic aspects underpinning the asymmetric Grignard synthesis of chiral tertiary alcohols, aimed at elucidating the possible intermediate species participating in the reaction mechanism, is currently underway and will be reported in due course.

Conclusions

In conclusion, we have developed a new class of N,N,O-tridentate chiral ligands for single-metal controlled asymmetric addition of Grignard reagents to ketones. The design methodology involves the introduction of a biaryl fragment in the ligand's structure, crucial for the control of stereoselectivity. The new biaryl ligands L7–L14 have been derived from 1,2-DACH through a divergent synthetic route involving efficient late-stage diversification of the common aryl bromide precursor L6 *via* palladium-catalyzed cross-coupling with a range of aryl boronic acids. The biaryl analogues L12 and L12', featuring an *ortho*-3,5-(bis-trifluoromethyl)phenyl substitution, emerged as new efficient and versatile chiral ligands, providing high to excellent enantioselectivities in the asymmetric 1,2-addition of alkyl Grignard reagents to ketones. Most crucial, L12 and L12'

resulted equally effective in promoting the addition of challenging aromatic Grignard nucleophiles, as opposed to the limited success characterizing the previous attempts with ligands L0 and L0'. These findings enabled, for the first time, the implementation of aromatic organomagnesium reagents in our asymmetric Grignard methodology and, in turn, to expand its scope to previously inaccessible targets. The optimization of the ligands preparation completed the method's development, by means of new one-pot synthetic sequences featuring improved yields and step-economy, together with easier procedures and faster operations. The new routes make use of cheap and widely available materials, ensuring the straightforward and cost-effective preparation and application of the DACH-ligands. The present study marks the finalization of the stoichiometric version of our asymmetric Grignard method. The performances achieved herein establish it as a general and broadly applicable strategy for the synthesis of chiral tertiary alcohols, enabling the modular and highly enantioselective construction of challenging tetrasubstituted stereocenters without the need for additional metal catalysts or additives. It is our belief that the asymmetric Grignard approach will facilitate the preparation of valuable bioactive targets and foster the underdeveloped use of chiral tertiary alcohols as versatile substrates and synthetic intermediates. Further studies are currently underway for the development of an effective catalytic version of the method.

- 20 The *N*-pyrrole ligand analogue (*R,R*)-**L12'** was prepared in three steps from **4·HCl**, see ESI†
- 21 Replacing the aryl alkyl ketone substrates **1** with methyl ethyl ketone **8**, gave a reasonable control of the enantioselectivity, producing the tertiary alcohol (*S*)-**2a** in 54% ee, thus demonstrating the ability of **L12** to exert effective chiral recognition in challenging substrates as **8**, with almost symmetrical structures, *i.e.* methyl vs. ethyl.

Acta*, 1976, **59**, 2462; (b) For clemastine synthesis *via* invertive aryl migration, see: A. M. Fournier, R. A. Brown, W. Farnaby, H. Miyatake-Ondozabal and J. Clayden, *Org. Lett.*, 2010, **12**, 2222; (c) *via* lithiation/borylation, see: J. L. Stymiest, V. Bagutski, R. M. French and V. K. Aggarwal, *Nature*, 2008, **456**, 778; (d) *via* rhodium-catalysis, see: L. Huang, J. Zhu, G. Jiao, Z. Wang, X. Yu, W. Deng and W. Tang, *Angew. Chem., Int. Ed.*, 2016, **55**, 4527; (e) *via* phosphoramidate-Zn(II) complex, see: M. Hatano, T. Miyamoto and K. Ishihara, *Org. Lett.*, 2007, **9**, 4535.
- 23 The development of the new formal synthesis of clemastine involved an extensive screening of conditions. The nature of the Grignard reagent RMgX was investigated, with regard to the halide functionality (X = Cl, Br and I) and the ethereal solvent. The Grignard reagents MeMgBr, MeMgI, *para*-chlorophenylMgBr and PhMgBr were used as Et₂O solutions, while PhMgCl was tested as THF solution, delivering comparable results. Finally, the study identified an alternative order of addition for the preparation of the intermediate (*R*)-**3a**, enhancing the enantioselectivity from 89% ee to 94% ee, see ESI† for further details.
- 24 Of particular interest is the possibility to access both enantiomers (*R*)-**3a** and (*S*)-**3a** with the use of a single ligand (*R,R*)-**L12**, by simply changing the synthetic disconnection, while keeping unchanged the stereochemical configuration of the source of chirality which, conversely, commonly accounts as a critical requirement in asymmetric synthesis.
- 25 It is worth to note that the determination of the absolute configuration of several tertiary alcohols products (*via* X-ray crystallographic analysis or by comparison with HPLC

and optical rotation data reported in the literature, Tables 2 and 4), showed the asymmetric induction of the new biaryl ligands **L12/L12'** to be consistent with the outcomes provided by the parent DACH-ligands **L0** and **L0'**, thus substantiating the previously proposed selectivity model (see ref. 12–14). In addition, the study validated the use of the method we previously developed for the determination of the absolute configuration of challenging chiral tertiary alcohols, *via* X-ray analysis of **13**, solid *para*-bromophenyl

carbamate O-derivative of alcohol **2h**, see ESI† for further details. For the early development of the chiral tertiary alcohol O-derivatization strategy, see ref. 14. Crystallographic data for (*R*)-**13** have been deposited with the Cambridge Crystallographic Data Centre [CCDC 2158994].

26 Crystallographic data for **C1** have been deposited with the Cambridge Crystallographic Data Centre [CCDC 2158472].
