The intricate, tightly controlled mechanism of wound healing that is a vital physiological mechanism is essential to maintaining the skin's natural barrier function. Numerous studies have focused on wound healing as it is a massive burden on the healthcare system. Wound repair is a complicated process with various cell types and microenvironment conditions. In wound healing studies, novel therapeutic approaches have been proposed to deliver an effective treatment. Nanoparticle-based materials are preferred due to their antibacterial activity, biocompatibility, and increased mechanical strength in wound healing. They can be divided into six main groups: metal NPs, ceramic NPs, polymer NPs, self-assembled NPs, composite NPs, and nanoparticle-loaded hydrogels. Each group shows several advantages and disadvantages, and which material will be used depends on the type, depth, and area of the wound. Better wound care/healing techniques are now possible, thanks to the development of wound healing strategies based on these materials, which mimic the extracellular matrix (ECM) microenvironment of the wound. Bearing this in mind, here we reviewed current studies on which NPs have been used in wound healing and how this strategy has become a key biotechnological procedure to treat skin infections and wounds.

1. Introduction

Wound healing is a vital physiological mechanism for preserving tissue integrity, following the formation of an acute or chronic wound (ulcer) that leads to tissue damage.¹ Long-term, and persistent wounds (chronic) produced due to the complications such as obesity, microbial infection, aging, or other factors may disrupt the tissue integrity and result in severe morbidity, and reduced quality of life.² Effective wound

healing strategies are challenging due to the requirement of complicated treatment strategies, along with increased medical expenses for clinicians and researchers.^{2,3} On the other hand, wound management has been identified by the World Health Organization (WHO) as a global public health concern.⁴ Wound repair is a complicated and staged process with known cell types (*e.g.*, neutrophils, macrophages, fibroblasts, and keratinocytes) and microenvironment conditions (*e.g.*, extracellular matrix (ECM) components, cytokines, and growth factors

(GFs)).^{3,5,6} Routine wound healing consists of sequential phases, including hemostasis, inflammation, proliferation, and remodelling phase.^{1,2} Following a skin injury, platelet aggregation is activated, resulting in degranulation and the release of chemokines and GFs to form the clots. Subsequently, macrophages accumulate at the site of injury, promoting the phagocytosis of pathogenic microorganisms. The proliferative phase is distinguished by an increase in the number of cells (*e.g.*, fibroblasts, keratinocytes, and endothelial cells) and abundant connective tissues (*e.g.*, proteoglycans, hyaluronic acid, collagen, and elastin). The remodelling phase (final stage) includes both current cells' apoptosis and cell production.¹

In wound healing studies, novel therapeutic approaches have been proposed with the aim to develop effective treatments that target different wound healing stages, or even the entire processes. Wounds demonstrate differences in terms of molecular and cellular mechanisms. Therefore, therapeutic strategies to treat these injuries are also diverse. Nano-therapeutic-based, stem cell-based, bioprinting-based, ECM-based, platelet-rich plasma-based, cold-atmospheric plasma-based, and microRNA-based therapies have come into prominence as recent options for wound healing.³ These strategies can be used to support the initiation/maintenance of the cells' functional expression, target collagen synthesis activation, angiogenesis activation, cytokine modulation, GF activation, antimicrobial effects, *etc.*⁷ Various types of nanomaterials, including metal NPs (*e.g.*, silver, gold, copper, zinc oxide, titanium dioxide, *etc.*), ceramic NPs, synthetic polymeric NPs (*e.g.*, PET, PLGA, PLLA, *etc.*), natural polymeric NPs (*e.g.*, chitosan, gelatin, silk, fibrin, collagen, *etc.*), self-assembled NPs, and composite NPs have been used for acute or chronic wound healing. All these strategies are covered in this review article.

The improvement of these nanomaterials, which imitate the wound ECM microenvironment, has opened the path for better wound care/healing therapies. The most significant reasons for the preference of metal NPs are that they are less toxic and present intrinsic bacteriostatic and bactericidal activity.⁸ Ceramic nanofibers are generally used with the integration of synthetic or natural polymers in wound repair approaches because of their bioactivity and biodegradability characteristics.⁹ Polymers with low toxicity are often used in tissue engineering and drug delivery applications through further modifications.¹⁰ Additionally, the biocompatible self-assembled NPs have vast potential to closely mimic the natural ECM that can be functionally developed to increase their communication with other cells.⁸

Moreover, as the focus of this review, hydrogels-NPs composites possess many advantages, including antibacterial properties, and providing a moist environment.¹¹ Recently, nanoparticle-loaded hydrogels for wound healing have attracted attention as a better option than standard dressing. Hydrogels also have natural healing qualities, including excellent water absorption, biocompatibility, and biodegradability properties. Furthermore, modern wound dressing systems prioritize natural polymer hydrogel dressings that can improve the wound microenvironment and promote healing at various stages.¹²

Considering all the above, this review is an update on current findings of wound healing from the perspective of nanoparticle strategies that are incorporated in hydrogel wound patches, aiming at better understanding the wound healing mechanisms for the development of more effective treatment strategies to maintain a regulated and coordinated inflammatory response at the injury site.

2. Wound healing and chronic wound physiology

Wounds are categorized into two groups: acute and chronic, which is determined by the healing time.¹³ Generally, if the healing time exceeds 12 weeks, the wound can be considered as chronic. However, in case the healing process reach 30 days, it can be categorized as a wound that does not show any signs of healing.¹⁴⁻¹⁶ The rate of healing depends on several internal and external factors. The lack of extracellular matrix (ECM) proteins, increased reactive oxygen species (ROS) production, worsening neovascularization, hypoxia, decreased collagen formation, and the attenuation of angiogenic growth factors can be considered as several reasons of reduced healing rate.¹⁷ Diabetic foot ulcers, pressure ulcers and vascular ulcers are examples of chronic wounds.¹⁴ The protective epithelium layer in the vicinity of the wound is injured, rendering it ineffective.¹⁸

The wound healing process consists of a linear set of stages. Delays in this flow cause an inflammation cycle, and the wound becomes chronic as a result.^{19,20} An increase in the number of M1 macrophages and neutrophils at the chronic wound site is generally caused by increased ROS, chemokines, cytokines, and other inflammation-related substances. The ROS and matrix metalloproteinase (MMPs) molecules released by these cells also contribute towards inflammation. As a result, scar tissues

Fig. 1 Phases of acute and chronic wound healing processes.

Review

are subjected to unremitting cycle of inflammation (Fig. 1). On the other hand, wound healing in acute wounds, consists of four stages: hemostasis, inflammation, proliferation, and remodelling.^{14,21} Nevertheless, it is worth noting that hemostasis is not considered as a different stage in several articles.^{16,22} At the hemostasis stage, clot formation is observed to stop bleeding and prevent blood loss *via* platelets at the wound site, which is no longer protected with an epithelial layer against external pathogens. It is a complex process involving many factors, including the conversion of fibrinogen to fibrin and the eventual formation of a fibrin clot that enables cell migration to the affected area.^{23–25} From that wound vicinity, calcium, ROS, microbe-associated molecular patterns (MAMPs), pro-inflammatory cytokines (mostly interleukin-1 β (IL-1 β), IL-6, and tumor necrosis factor α (TNF- α), and damage-associated molecular patterns (DAMPs) such as ATP, DNA, or uric acid are released either directly or indirectly to stimulate migration to these regions.^{13–16,26,27} For instance, in response to these factors, innate macrophages release hydrogen peroxide (H₂O₂), which is a ROS that promotes inflammation (*e.g.*, *via* nuclear factor κ B (NF- κ B))²⁶ and, subsequently, causes migration.²⁸ Consequently, pro-inflammatory responses are activated, leading to the second stage of wound healing (inflammation).²⁴ To break down the damaged ECM, to offer defense against external pathogens, and to clear debris, several cell types such as neutrophils and monocytes are recruited to the affected area.^{27,29,30} These inflammatory cell types are localized in certain regions by tracking elevated pro-inflammatory factors.^{26,27,31} Neutrophils are a type of migrating cell that secrete and/or are activated by cytokines, including leukotriene B₄ and chemokines like CXC motif chemokine ligand 8, IL-1 β , IL-6, IL-10, IL-17, and TNF- α *via* various pathways (*e.g.*, NF- κ B, phosphoinositide-3-kinase, extracellular signal-regulated kinase, RAC).^{27,32–34} Additionally, they use various strategies, including phagocytosis, ROS or granules release, and the construction of neutrophil extracellular traps that have antimicrobial properties and are capable of secreting proteases.^{19,26,27,33–38} By contrast, MMPs digest damaged ECM.²⁸ While innate macrophages are present at the site of the wound, monocytes, which represent another class of migratory cells, predominantly transform into pro-inflammatory (M1) macrophages.^{29,35} M1 macrophages secrete MMP-2, MMP-9, and cytokines, including IL-1, IL-6, and TNF- α .^{26,36} Pro-inflammatory cells migrating to the affected area through inflammatory mediators enhance the inflammatory response, leading to increased inflammation. For example, macrophages secrete MMPs and cleave the ECM, increasing the number of DAMPs molecules in the wound area, whereas neutrophils release ROS.^{36,39,40} When the wound area lacks unnatural substances, the pro-inflammatory cells must be cleared, so that the wound can recover properly and completely.^{34,39}

There is more than one way to clear neutrophils: either by re-entering the bloodstream or by macrophages phagocytosis after neutrophils have gone through the necrosis and/or apoptosis pathways.^{34,41} By contrast, M1 macrophages can transform into anti-inflammatory (M2) macrophages and participate in the following proliferation stage in accordance with the normal

healing timeline.^{19,29,42,43} These systems are vulnerable to disruption.¹⁹ It is mentioned that macrophages' ability to phagocytize neutrophils may be reduced, or the transition between types of macrophages can be inhibited.^{29,44–46} For example, in the regular wound healing process, SETDB2, which silences pro-inflammatory cytokine genes by methylating the NF- κ B binding sites of those gene promoters, increases their expression after four days. As demonstrated by Gallagher and colleagues, this pathway is induced by high amounts of interferon (IFN)- β and causes M1 to transform into M2.⁴⁶ However, in diabetic patients, the impairment starting from that up-regulation of IFN- β causes an increase in pro-inflammatory cytokines, along with an increase in uric acid production.^{46,47} Sustained inflammation is caused by disruptions in pro-inflammatory mechanisms, including neutrophil clearance or the transition between M1 and M2 macrophages, as might be seen in chronic wounds.^{19,20,48,49} In chronic wounds, the oxygen pressure can be as low as 10 mm Hg, which is lower than in normally healing wounds. The hypoxia is caused by a defective angiogenesis mechanism.^{50,51}

Proliferation phase is composed of four steps: re-epithelisation, angiogenesis, granulation of tissue formation, and collagen deposition.³⁸ A provisional matrix is formed by fibrin and fibronectin, and then keratinocytes and epithelial cells multiply move across ECM to begin the re-epithelization process.^{52,53} Angiogenesis is required to supply enough oxygen and nutrients to the wound area.^{53,54} Macrophages aid angiogenesis by secreting TGF- β (transforming growth factor) and VEGF (vascular endothelial growth factor).⁵⁵ Also, collagen I induces angiogenesis by attracting endothelial cells.⁵⁶ Fibroblasts degrade provisional matrix and create granulation tissue, which helps the wound space closure by secreting collagen, fibronectin and hyaluronic acid.^{30,57}

During the granulation of tissue formation, macrophages, fibroblasts, and blood vessels are recruited.^{58–60} Collagen fibers that are produced by fibroblasts to form granulation tissue are irregular. They are first disintegrated using enzymes produced by neutrophils, macrophages, and fibroblasts. These fibers then adopt a more structured appearance. The arranged fibers begin to deposit at the end of the proliferation phase, starting the remodeling phase.^{24,38}

The remodeling stage is the final stage of wound healing, which can take years.⁶¹ The granulation tissue turns into scar tissue by transformation of fibroblasts into myofibroblasts. Myofibroblasts secrete α -SMA (α -smooth muscle actin), which leads to elevated mechanical strength.⁶² Also, type III collagen converts to type I collagen, which has a higher tensile strength; however, the scar tissue recovers about 50–80% of their tensile strength.^{61,63} In chronic wounds, ECM cannot be regenerated properly due to excessive MMPs, an unbalanced ratio of protease inhibitors that cause a persistent inflammatory environment.¹⁹ The inflammatory environment enhances ROS production that induces cell damage.^{39,64} Thus, many senescent cells are localized in chronic wounds.¹⁹ By contrast, microbial contamination that causes biofilm formation, which is known to be drug resistant, is present in the chronic wound environment. The most common microorganisms are *Enterococcus*

faecium, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa* and *Enterobacter* sp., known as the “ESKAPE” group of pathogens.^{65–67} Even fungal biofilms exist in chronic wounds, although their mechanisms and biological roles have not yet been fully understood.⁶⁸

3. Nanoparticles in wound healing

3.1. Metal nanoparticles

The exploitation of metals as antibacterial agents is traced back to early civilizations. During the past ten years, the use of metals and metal NPs to fight infection has increased. Numerous metal NPs are now easily accessible on the market and utilized more regularly in hospitals for dressings.⁶⁹ Metal NPs like silver, gold, and zinc are the main options for wound dressing's development because of their antibacterial capabilities and low toxicity.⁷⁰

3.1.1. Silver nanoparticles. *In vitro* antimicrobial activity studies on silver NPs (AgNPs) are comprehensive. AgNPs have remarkable antimicrobial properties and specific physico-chemical characteristics (high surface area to mass ratio), which provide them with a significant advantage in the evolution of different options against multidrug-resistant microorganisms.⁷¹ Silver NPs may be combined with antibiotics at low quantities to boost effectiveness, while minimizing adverse effects. In a recent report, it was shown that using AgNPs and tetracycline together greatly reduced the load of microorganisms in a mouse model's surface and deeper tissue regions, thus accelerating the healing process.⁷¹ The antibacterial characteristic of silver is well recognized for being regulated *via* the blocking of respiratory enzyme pathways and modifying the microbial DNA and cell walls.⁷² Moreover, AgNPs increase wound contractibility by stimulating the segregation of myofibroblasts from normal fibroblasts and speeding up the recovery process.⁷³

The antibacterial effect of Ag⁺ ions also comes from their interaction with sulphur and phosphorus groups within the structure of bacterial cell walls and plasma membrane proteins, which causes these proteins to malfunction.⁷⁴ By contrast, silver ions directly bond to the cell membranes, and the deposition of silver upon negatively charged regions of the cell surface causes membrane rupture, intracellular content leakage, and cell death.⁷⁵ The activity of the bacteria's electron transport chain may then be hampered by the existence of silver ions inside the cell. Moreover, silver ions bond to the bacterial DNA and RNA and block cell division.⁷⁶

Nanobiocomposite (NBC's) hydrogels were developed by R. Singla *et al.*⁷⁷ using bamboo cellulose nanocrystals combined with AgNPs. As a result, this hydrogel enhanced the recovery process in just 18 days.⁷⁷ Also, several clinical experiments involving wound healing, particularly burns and chronic wounds such as diabetic ulcers, used silver NPs.⁷⁸

3.1.2. Gold nanoparticles. Gold NPs (AuNPs) are suitable materials for treating wounds because of their simple synthesis, chemical stability, and unique optical properties.⁷⁹ The antibacterial and antioxidant activities of AuNPs can drastically accelerate wound healing and repair damaged collagen tissues.⁸⁰ This anti-inflammatory and anti-angiogenic effect of

AuNPs stimulates the release of proteins that are essential for wound healing.⁸¹ AuNPs are useful in biomedical activities, as different biomolecules should be integrated into them. Among the benefits to biomedical application, we can cite that fact that different biomolecules can be integrated into these structures. The inclusion of the gold surface does not cause a change in the structure of the collagen–collagen crosslink, which means that cooperating with polysaccharides, growth factors, peptides and molecules will provide benefits in terms of adhesion to cells. These modified AuNPs exhibit characteristics including biocompatibility and biodegradability, making them useful in various applications involving wound healing. Comparable to collagen, chitosan, and gelatin, these substances may also be added to AuNPs, showing good results in accelerating wound healing.^{82,83}

Regarding their bacteriostatic and bactericidal effects, AuNPs can either target interfere with the bacterial cell wall integrity, or they can bind to the double-helix of bacterial DNA and stop it from unfolding throughout transcription or replication. Therefore, they can inhibit bacteria that are multidrug resistant, including *Escherichia coli*, *S. aureus* and *P. aeruginosa*. Besides, AuNPs also act as antioxidants by preventing the development of ROS and accelerating curing.⁸⁴ Also, according to some studies, AuNPs had a significant impact on the healing of wounds by successfully scavenging free extremist like DPPH (2,2-diphenyl-picrylhydrazyl), OH (hydroxyl), H₂O₂ (hydrogen peroxide), and NO (nitric oxide).^{85–87}

In the context of bacterial infections, vancomycin-combined gold NPs (Au-Vanc-NP) massively improved vancomycin's effectiveness over *E. coli*.⁸⁸ For photothermal treatment⁸⁹ or photodynamic therapy (PDT),⁹⁰ AuNPs can be conjugated with pathogen-specific antibodies or photosensitizing compounds.

3.1.3. Copper nanoparticles. Copper is a necessary component in many wound-healing processes.⁹¹ Copper enhances healing through raising the levels of ECM particles such as fibrinogen, collagen, and integrins, which are the principal mediators of cell attachment to the ECM.⁹² The copper-induced activity of vascular endothelial growth factor (VEGF) is recognized to support angiogenesis in wounds.⁹³ Copper NPs (Cu NPs) can also promote angiogenesis *via* influencing the expression of hypoxia-inducible factor (HIF-1a) and the control of VEGF.⁹⁴

CuNPs have been produced using a variety of methods, including sonochemical methods, metal vapour deposition, electrochemical reduction, radiolytic reduction, thermal decomposition, mechanical attrition, laser ablation, micro-emulsion techniques, and chemical reduction.⁹⁵ The chemical reduction method is one of the most universal for fabricating metal NPs due to its low cost and convenience.⁹⁵

Generally, copper-containing nanomaterials show excellent activity in wound dressings and can be potentially used in biomedical applications.⁹⁶ Alizadeh and his colleague observed that 21 days exposure of CuNPs (80 nm/1 mM), could efficiently enhance the wound healing process within the treated rats than the rats in control set.⁹⁴ Cu has the ability to speed up the skin healing process in mice by increasing VEGF expression at the wound margin.⁹⁷ Copper-containing biologically active egg shell

membrane nanocomposites were found to increase *in vivo* angiogenesis rate and generate neo-epidermis, which are beneficial to wound healing.⁹⁸

3.2. Ceramic nanoparticles

Several advanced nanocomposite hydrogel systems can be obtained by integrating natural or synthetic polymers with ceramic NPs that have a high variety of options such as silica, hydroxyapatite and metal oxides.^{99,100} These nanocomposites will be discussed in detail in the following topics.

3.2.1. Silicon derived ceramic nanoparticles. Silicon and its derivatives are preferred in bone tissue applications due to their ability to promote osteogenic differentiation in human stem cells and collagen type I synthesis.¹⁰¹ Silicon dioxide is also known to support bone regeneration. For instance, silicon dioxide derived bioglass materials have shown to promote regeneration by forming apatite bonds on surface layer.¹⁰²

Silica is a type of mineral that is obtained from silicon dioxide, which is known to be non-toxic and highly biodegradable.¹⁰³ When integrated with hydrogel systems, they have shown to promote wound healing with different aspects. For instance, silica-collagen type-I nanocomposite hydrogels have been formed by encapsulating two types of antibiotics into silica NPs (SiNP). These nanocomposites have been immobilized at high silica dosage in concentrated collagen hydrogels without changing their fibrillar structure or affecting their rheological behavior. Additionally, it was observed that their proteolytic stability was increased.¹⁰⁴ By contrast, Öri and colleagues designed SiNP-PVP nanocomposites that fastened re-epithelization and promoted the wound healing property of silica-based nanomaterials.¹⁰⁵

Another research area related to nanocomposites is adjoining cut wounds and different tissue adhesives. A simple aqueous solution of SiNPs was developed by Rose *et al.*,¹⁰⁶ which was efficiently used as a tissue adhesive for *ex vivo* bonding of natural bovine tissue. The same group has further refined it as a nanobridging technology for fast and powerful closure and healing of deep wounds in the skin and liver of mice.¹⁰⁶ In addition, another study found that SiNPs helped skin fibroblast cells proliferate and spread to the injured area, released silicic acid, and improved topical wound repair *in vitro*.¹⁰⁴ The very rapid release of loaded drugs in some polymeric structures (*e.g.*, collagen) has a serious limiting role in areas such as wound dressing. Due to this limitation, silica NP integrated systems have been developed to enhance the controlled drug release.

Mesoporous silica NPs (MSNPs) are acknowledged as ideal candidates to drug carriers and promote wound healing due to their high surface area-to-volume ratios. It has been shown that basic fibroblast growth factor (bFGF) encapsulation into MSNPs is possible, revealing high loading capacity and a highly controlled release capacity. Reportedly, bFGF-loaded MSNPs were capable of increasing bone regeneration and revealed a promising system for wound healing.¹⁰⁷

Silicates are mainly salts containing anions of silicon and oxygen. Wang *et al.*¹⁰⁸ reported that the acceleration of diabetic wound healing has been demonstrated through the release of

the silicon ions from silicate-based bioceramics during their degradation. The basic form of silicate-based biomaterials mainly includes silicate bioactive glass and bioceramic powders. Typical silicate biomaterials for wound healing are silicate-based bioglass or bioceramic powders combined with natural or synthetic polymers to produce hydrogels.^{108,109} They can also be loaded with clotting factors and due to their charged interactions; they can induce blood clotting and, therefore, can be used as homeostatic agents.¹¹⁰

Studies have reported an alendronate (ALN)-Ca²⁺/Mg²⁺-doped supramolecular (CMS) hydrogel that improved the hydrogel's mechanical properties and osteogenic activity. Moreover, encapsulated bioglass particles in oxidized sodium alginate (OSA) cross-linked with adipic acid dihydrazide (ADH) modified γ -polyglutamic acid, and bioglass NPs creating an alkaline micro-environment providing the hydrogel stickiness to different medical implants.^{111,112} Recent studies have shown that silicate-based biomaterials actively promote wound healing by regulating the function of various skin-related cells. It has been proven that such bioactivities are attributed to bioactive ions released from wound dressings.^{113,114}

Chitosan-based injectable systems containing bioactive glass NPs are silicate derivatives that induce the formation of bone tissue that integrates well with the hydrogel structure that have played an important role in stimulating cell proliferation, angiogenesis and wound healing.¹¹⁵ Some other studies have shown that bioactive glass NPs can bind to soft tissue through the apatite layers formed on their surface when they come into contact with cells.¹¹⁶ Mao *et al.*¹¹⁷ investigated the effect of bioglass on cultures of human umbilical vein endothelial effects (HUVECs). As a result, the bioglasses stimulated HUVEC proliferation, accelerated cell migration, and up-regulated maintenance of endothelial NO synthase.¹¹⁸

Nanoclays are composed of NPs of layered mineral silicates with exceptional mechanical properties containing the minerals found in bone tissue. These nanomaterials can successfully interact and disperse within networks of polymeric hydrogels, due to their interaction capacity.¹⁰⁸ They have been researched on traumatic wounds that require fast homeostasis and it was shown that injectable nanosilicate-gelatin hydrogels decrease *in vitro* blood clotting 77% and it formed stable clot-gel systems under *in vivo* conditions.¹¹⁹ In addition, the integration of nanosilicate to collagen stabilizes the nanocomposite network due to strong physical interactions.

Nanocomposite hydrogels have also been shown to promote tubule formation of cultured endothelial cells.¹¹⁸ Synthetic silicate nanoplatelets such as LAPONITE® (Lap), which is a commercial name for synthetic nanoclay, are highly charged NPs that have been shown to induce blood coagulation. It has been proven that Lap can support bone mineralization without the help of external growth factors (GFs). Due to the presence of both positive and negative charges on the nanosilicate surface, they interact strongly with proteins and the presence of these strong ionic interactions mean that chemical conjugation is not required. It has been shown that the incorporation of vascular endothelial growth factor (VEGF) into Lap-collagen gel enhances angiogenesis *in vivo*. The ability of the nanocomposite

gel to increase angiogenesis can be used to promote wound healing.¹¹⁸ Therefore; Lap-coupled hydrogels have emerged as promising options for applications such as tissue engineering and wound healing without the need for GFs. Moreover, it has been reported that the integration of Lap and polyethylene glycol (PEG) stimulated cytoskeletal arrangement and cell binding.¹²⁰ It was shown that Lap is a potential antibacterial agent and assists in homeostatic processes. Moreover, it can also be used to encapsulate drug-like molecules.¹²¹ Studies have also shown that mafenide (Maf) can be added between layers of nanosized Lap to be used as an antibiotic elution gel for healing burn wounds. The film showed a water absorption capacity higher than alginate alone.¹¹⁹

45S5 is one of the most representative bioglasses. It has been used for bone tissue regeneration osteogenesis stimulation, and angiogenesis promotion at a high rate.¹²² This system is useful for acute wounds,¹²³ chronic wounds,¹²⁴ infected wounds,¹²⁵ and burns.¹²⁶ Mesoporous bioglasses (MBGs) have also been used extensively to repair bone tissues, as they form a direct and firm bond with living tissues. To repair large bone defects, porous structures with proper vascularization that can allow migration and proliferation of osteoblasts are critical. Studies have shown that (PEGSH)₄ homopolymer MBGs form an injectable and self-healing dynamic hydrogel for bone regeneration. It has also been observed that the dimensions, surface areas, surface chemistry and other properties of MBGs will significantly affect the biocompatibility and mechanical properties of the prepared bioink.¹²⁷

3.2.2. Calcium and phosphate salts. Calcium phosphate NPs can be easily combined with different polymers to form a hydrogel mesh. With this hydrogel complex, bone regeneration can be achieved with promoted angiogenesis and osteogenesis. Also, they have shown to enhance drug release and antibacterial effect. It has been shown that bicalcium phosphate (BCP) NPs combined with chitosan/gelatin hydrogels form bone scaffolds for bone tissue engineering.¹²⁸ In that study, physicochemical and biological properties were investigated by preparing chitosan/gelatin/BCP NPs in different weight ratios.¹²⁸ It was observed that the porosity, swelling rate and mechanical strength of 3D printed bone scaffolds were mainly affected by the dosage of BCP NPs. In addition, in the same study, it was shown that BCP NPs can improve the hMSC proliferation of scaffolds and, therefore, have a great potential in bone tissue engineering both *in vitro* and *in vivo*.¹²⁸

Tricalcium phosphate (TCP) can be cited as another example. There are two main types of TCP: α -TCP and β -TCP. Because β -TCP is more stable than α -TCP, it is more commonly used as a bone scaffold. β -TCP NPs can promote the mechanical functioning of bone structures and proliferation of osteoblasts. These qualities predominate β -TCP in bone scaffolds.¹²⁹ In active and rapid chemical regeneration, the support is obvious as they are the main minerals in the bone structure and, therefore, β -TCP NPs have been integrated into the PEGylated specific membrane.¹³⁰ In that study, the membrane exhibited a controllable degradation rate and enhanced mechanical properties based on different β -TCP dosages. It is believed to be

capable of promoting the adhesion and proliferation of rat bone marrow-derived mesenchymal stem cells (rBMSCs).¹³⁰

Hydroxyapatite is a natural form of calcium apatite that is found in the nature. It is known to support homeostasis, prevent inflammation and promote proliferation and re-epithelization.¹³¹ It also provides high mechanical strength.¹¹¹ Due to their high physiological stability, HA structures are preferred as injectable fillers in orthopaedic applications. Moreover, considering its highly elastomeric structure, it provides control on tissue viscoelasticity.¹³²

3.2.3. Metal oxides. Metal oxides are one of the most important and widely characterized classes of ceramics. Some of the most used types of metal oxides for wound healing applications are zinc oxide (ZnO), titanium dioxide (TiO₂) and zirconium dioxide (ZrO₂).

Due to their high mineral content and combinability, magnesium oxides (MgO) and aluminium oxides (Al₂O₃) are promising candidates for tissue healing applications.¹⁰⁸ Furthermore, metal oxides such as copper oxide (CuO) and NO are known to act as antibacterial agents and promote wound healing.¹³³

3.2.3.1 Zinc oxide nanoparticles. Zinc oxide NPs (ZnO NPs) are used in numerous hydrogel-based wound treatments due to their exceptional antibacterial characteristics.¹³⁰ ZnO is known to regulate homeostasis¹³¹ and high antibacterial potential.^{119,134} The antibacterial efficacy of ZnO NPs with diameters of 20 nm, 70 nm, and 100 nm was quantified against Gram-negative (*E. coli*) and Gram-positive (*S. aureus* and *B. subtilis*) bacterial strains.¹³⁵ ZnO NPs are far more effective against Gram-positive bacteria, most probably due to its interaction mechanisms with bacterial cell walls that lack lipopolysaccharides (LPS).¹³⁵ The utilization of ZnO NPs is beneficial because of its significant activity against harmful bacteria even at low concentrations. Moreover, they are long-lasting, with high selectivity and temperature resistance.¹³⁶ It is also antineoplastic, promoting keratinocyte mobility, angiogenesis and wound healing.^{134,137} Due to these characteristics, it is mainly used for the control of inflammation during wound healing.¹³⁸ Studies have shown that ZnONPs exhibit therapeutic activities against bacterial infection and inflammation, and showed potential for wound healing applications.¹³⁹

Zinc is one of the most important trace elements that regulate burns and slow-healing wounds through regulation of DNA and RNA polymerases, ribonuclease and thymidine kinase. It has been reported that it has low toxicity but preserving its permeability in engineered chitosan–ZnONP hydrogels. These dressings have been reported to have excellent biocompatibility, inhibit bacterial growth, and improve wound closure *in vitro* and *in vivo*.^{140,141}

3.2.3.2 Titanium dioxide nanoparticles. Titanium dioxide NPs (TiO₂NPs) are appropriate for the recovery of wounds materials due to their bactericidal and anti-inflammatory activities, higher bump, hydrophilicity, and biocompatibility. Bacterial cellulose (BC) and TiO₂ were conjugated by Khalid *et al.*¹⁴² to create nanoconjugates that may be used as bandages for wounds.¹⁴² In that work, the authors noted that BC was highly water-retentive, porous, and biocompatible, making it an

ideal material for wound care applications. The same research group also demonstrated that incorporating TiO₂NPs into BC improved its potency as a material for wound treatment. The biocompatibility and antibacterial activity of these newly created nanocomposites were increased. Similarly, a synthetic skin-equivalent nanocomposite from chitosan and TiO₂ was produced. Such synthetic skin substitutes show low density, good thickness, moderate biodegradability, and adequate water absorption capabilities. Also, it was seen that the titanium increased the strength and showed excellent antimicrobial effects on pathogenic bacteria whilst increasing wound healing in albino rat models.¹⁴³

Additionally, Sivaranjani *et al.*¹⁴⁴ produced TiO₂NPs from *Moringa oleifera* leaves under optimum conditions. Upon analysis, it was discovered that the NPs were 100 nm in size. TiO₂-NPs have improved wound healing and acted as an antibacterial agent against Gram-positive and Gram-negative bacteria because of their superior mechanical properties.¹⁴⁴ Future research will benefit from these findings, and wound care products may use TiO₂NPs.

ZrO₂ and TiO₂ are also known to promote bone regeneration.¹⁴⁵ This combination has displayed improved antibacterial properties and increased mechanical strength through ROS production. In this context, it has been stated that it accelerates the healing of open excision wounds.¹⁴⁶ It has been shown that TiO₂NPs promote wound healing through the production and secretion of critical molecules for the process.¹⁴⁷ Moreover, wound dressings made out of TiO₂NPs showed an improvement in structural, textural, thermal, optical, mechanical, vapour barrier properties and their biodegradability in a dose-dependent manner.¹⁴⁸

3.2.3.3 Magnesium oxide nanoparticles. Investigations on the role of magnesium oxide nanoparticles (MgO NPs) on wound healing were intensified due to their biocompatibility, low toxicity, thermal stability and antibacterial properties. In a study, carboxymethyl cellulose hydrogels containing magnesium hydroxide nanoparticles (Mg(OH)₂ NPs) were produced as a scaffold owing to increased wound healing as well as antibacterial activity.¹⁴⁹ In a separate study, Qu *et al.*¹⁵⁰ designed a hybrid nanocomposite hydrogel composed of MgO NPs and chitosan. They observed excellent mechanical properties, high biocompatibility, and improved antibacterial activity. Their results showed that the integration of MgO NPs significantly enhances *in vivo* wound healing process in a skin defect rat model.

3.2.3.4 Aluminium oxide nanoparticles. Aluminium oxide nanoparticles (Al₂O₃ NPs) are one of the metal oxides that have antibacterial activity.¹⁵¹ Tanveer and colleagues¹⁵² designed a biodegradable superabsorbent hydrogel derived from acrylic acid and Al NPs exhibited antibacterial activity. Rahmanpour *et al.* reported that the potential of TiO₂/Al₂O₃/Chitosan nanocomposites as effective and multi-functional dressings for the treatment of infected wounds, exhibiting antibacterial activity, reduced bacterial count, decreased expression of inflammatory genes, and increased expression of proliferative genes, fibroblast, and collagen, thus highlighting their promising healing capabilities and potential as a competitive alternative to

commercial ointments.¹⁵³ There are studies in which tubular aluminium oxide particles, grown in a contiguous manner using an anodizing system, are employed as molds for the production of nanopatterned polymer surfaces, presenting a novel perspective. For example, Altuntas *et al.* worked on multiple studies regarding osseointegration and wound healing have demonstrated that chitosan:gelatin nanorods, which take the form of the Al₂O₃nanotubes, play a beneficial role in these processes.^{154,155}

3.2.3.5 Copper oxide nanoparticles. Copper ions promote wound healing due to their promotion of angiogenesis. During the applications, one possible outcome for the patient is the potentially toxic levels due to the exposure to copper ions. Due to this risk and to develop a potential system that may eliminate this toxicity, researchers have designed a novel antioxidant copper metal-organic framework-thermo responsive polydiolcitrate hydrogel composite that accelerates chronic wound healing with reduced toxicity and apoptosis in a splinted excisional wound healing diabetic mouse model.¹⁵⁶ Another study, Li *et al.*¹⁵⁷ designed a hydrogel system including CuO NPs that increased antibacterial effects and skin tissue regeneration due to the ions release from the hydrogel stimulating proliferation and angiogenesis.

3.2.3.6 Cerium oxide nanoparticles. Non-healing wounds in patients with diabetic complications are a major issue that frequently leads to amputations and death. Cerium nanoparticles, in this connection, have exhibited potential results in several experimental studies.¹⁵⁸⁻¹⁶¹ Diabetic wounds are distinguished by impaired wound healing as a result of elevated oxidative stress, anomalies in its defence mechanism and prolonged inflammation.

Notably, biodegradable and highly porous gelatin methacryloyl hydrogel patches combined with cerium oxide NPs have showed promising exudate uptake capability, ROS scavenging activity, *in vitro* cellular proliferation (*i.e.* keratinocyte, fibroblast *etc.*), and *in vivo* mechanisms of diabetic wound healing.¹⁵⁹ Cerium NPs-miR146a composite raises wound collagen, improves angiogenesis, and reduces inflammation as well as oxidative stress, eventually encouraging faster wound closure in diabetic wounds.¹⁶⁰ Furthermore, chitosan/PVA hydrogels combined with Cerium NPs could be a competing candidate as a strong wound dressing material that effectively reduces infection without the usage of antibiotics.¹⁶¹

3.3. Polymer nanoparticles

Polymer NPs have gained significant attention over the last few years because of its size-related properties.¹⁶² Polymer NPs are in the family of nanocarriers (nanoparticle-based drug carriers). Nanocarriers also include lipid-based nanocarrier (liposome or micelle), gold (Au) NPs (nanoshell or nanocage), magnetic nanoparticle, carbon nanoparticle (nanotube), quantum dot, dendrimer *etc.*^{163,164} Nanocarriers are used for drug delivery applications. Herein, the polymer NPs provide safeguarding and managing controlled release of drugs, as well as increase the bioavailability and the therapeutic index.¹⁶⁵ They are advantageous over other nanocarriers because of easy

fabrication, cost-effectiveness, biocompatibility, biodegradability, non-immunogenicity and water solubility. In comparison to cationic lipids, cationic polymer generates a more stable complex which aids the cellular migration.¹⁶³

Polymeric NPs can be used in the form of either nanocapsules or nanospheres, and also in the form of carrier system with diameter less than 1 μm .¹⁶⁶ Nanocapsules are based on a lipid core enclosed within a polymeric shell. The drugs are typically dissolved within the lipid core and the shell regulates controlled drug release from the core.¹⁶⁷ The lipid core composed of vegetable oil or fatty acids acts as lipophilic drug-dissolving medium, facilitates the encapsulation of lipophilic chemical compounds and act as an alternative therapeutic. It is also possible to create polymeric nanocapsules with an aqueous core that will serve as a platform for the controlled delivery of hydrophilic compounds.¹⁶⁷ Nanospheres are comprised of matricial network of polymeric chains where the drug may adhere to the surface or be preserved within.^{165,168} Polymer NPs have a size distribution ranging from 10 nm to 100 nm, a positive or negative surface charge, a significant drug carrying capacity and diverse component matrices.¹⁶⁹ Its component matrices can be either synthetic (*e.g.*, poly-caprolactone) or natural (*e.g.*, gelatin or chitosan). They can be synthesized from nonbiodegradable materials (*e.g.*, cyanoacrylate or poly(lactic-co-glycolic acid)) or biodegradable materials (*e.g.*, polyurethane).¹⁶⁹ These nanostructures demonstrate significant drug loading efficiency for a wide range of drugs. One of the most widely used polymers for generating NPs is poly(lactic-co-glycolic acid), as it presents beneficial properties, including biocompatibility, biodegradability, and non-toxicity. Moreover, surface PEGylation is frequently employed to extend their *in vivo* half-life. As a result of surface-tuning of these NPs with PEG chains, the immunogenicity is significantly decreased as well as the stability and longevity is increased. Also, the aqueous solubility is improved, and opsonization is minimized.¹⁶⁹

Several biological applications, including anti-inflammatory therapy, anti-cancer therapy, and immunotherapy, use nanocapsules or nanospheres as delivery vehicles for preserving and encapsulating metabolites, peptides, enzymes, hormones, genes, and other pharmaceuticals.^{164–169} Polymeric NPs also involve organ targeted drug delivery and genetic drug delivery to alter the central dogma of the cell along with bioimaging, biosensing and theragnostic applications in clinical settings.^{170–172}

3.4. Self-assembled nanoparticles

The mechanism of self-assembly is the organization of the nano-sized molecules such as polymers, peptides, nucleic acids, and other NPs.¹⁷³ Various processes lead to the synthesis of self-assembling in ordered structures for gaining fully function of the molecules in living cells, causing several biological changes. The main processes comprise the enzyme instructed self-assembly such as alkaline phosphatase induction, polymerization-induced self-assembly that comprises another intracellular alteration, host–guest interaction as non-covalent interactions, and pH-changes.¹⁷⁴ The self-assembly processes can also be stimulated artificially to control biological

mechanisms in living cells.¹⁷⁵ Consequently, nanotechnological advances around self-assembled systems present features of structural adjustability, biocompatibility and functionality that are of great significance.^{176,177} They focus on improving treatment strategies,¹⁷⁸ vaccination,^{179,180} wound healing,^{177,181} DNA origami-nanorobot for drug nanodelivery system,^{182,183} disease detection applications,¹⁷² neural tissue repair,¹⁸⁴ and other nanoscale therapeutic delivery systems.¹⁸⁵ Self-assembled NPs represent the most potential cost-efficient and high-throughput practical technique to nano-production.¹⁷⁵

Self-assembled NPs especially used for wound healing strategies can be classified according to its material types, including metal, peptide amphiphiles, peptide-based self-assembled NPs, and elastin-like polypeptides. The fabrication methods can be divided into three major mechanisms: spontaneous (non-covalent) self-assembly, enzyme-catalysed self-assembly and chemical/physical cross-linked self-assembly.¹⁷⁷

Metal-based self-assembled NPs are the prominent biomaterials in wound healing studies, primarily attributable to their antibacterial effects. In 2015, Chen *et al.* developed 2.5 nm hybrid nanodots *via* immobilization of self-assembled antimicrobial lipopeptides (surfactin, SFT) with 1-dodecanethiol (DT) anchored gold NPs (Au). The hybrid nanodots demonstrate excellent antibacterial properties for multi- and non-multi-drug resistant bacteria. Moreover, it is worth highlighting the impact of SFT and DT/Au-nanodots synergistically. The underlying mechanism of this is through bacterial membranes damage. *In vivo* experiments with SFT/Dt-Au nanodots revealed that bacterially infected wounds healed quicker and constituted improved epithelization, and it was productive in terms of collagen fiber formation.¹⁸⁶

In another study, an antibacterial hybrid silver nanoparticle was developed as an alternative therapeutic strategy for wound healing. *In vitro* and *in vivo* studies demonstrated that this hybrid material which is formed by the incorporation of magnetic carboxymethyl cellulose- ϵ -polylysine hybrids (FCE) and silver nanoparticles (Ag NPs), has superantibacterial and wound healing promoting effects.¹⁸⁷ Moreover, in a study by Perez-Rafael and co-workers, silver-incorporated NPs were developed for chronic wound healing. The developed nanomaterial is an injectable self-assembly of hyaluronic acid (HA) modified with 2-iminothiolane, mixed with bioactive silver-lignin NPs in physiological conditions, as shown in Fig. 2A. Because of the silver-lignin NPs in its construction, this combined multifunctional hydrogel demonstrated high antioxidant and antimicrobial characteristics. Moreover, these biocompatible hydrogels block myeloperoxidase and matrix metalloproteinases. Furthermore, in *in vivo* experiments with a diabetic mouse model skin integrity restoration and remodelling were observed.¹⁸⁸

By contrast, a chimeric non-metallic nanocomposite composed of phenolated-lignin, thiolated-HA, and silk fibril (Fig. 2B) showed around 52% of disruption of myeloperoxidase and matrix metalloproteinases enzymatic event, which is associated with the wound chronicity. Indeed, this self-assembled hydrogel showed high *S. aureus* and *P. aeruginosa* load reduction. Additionally, cell viability assays conducted with BJ5ta

fibroblasts and HaCaT keratinocytes cell lines revealed approximately 93% of cell viability. Therefore, this mechanically and functionally tunable dressing material has a high potential for wound treatment.¹⁸⁹

The tripeptide glycyl-L-histidyl-L-lysine (GHK)-Cu NPs has been shown to promote wound healing and repair DNA damage. At the same time, its instability in physiological condition limits its applications. The physical structure of GHK-Cu NPs has gained fluorescence characteristics. The research on fluorescent GHK-Cu peptides has a potential to create novel fluorescent peptides class to advance healing strategies.¹⁹⁰ Additionally, growth factors have role in chronic wound healing process, and have also been combined with self-assembly peptides.¹⁹¹ The RADA 16-I nano hydrogel, which includes PDGF-BB incorporated ionic self-complementary peptide (RADARADARADARADA), is one of the examples. This self-assembled hydrogel showed capability for angiogenesis and chronic wound healing in cell culture and animal studies, offering a high potential strategy for wound treatment.¹⁹¹ Naturally small molecules such as gallic acid, a natural polyphenol having anti-inflammatory and antibacterial properties was used as a self-assembled NPs to accelerate wound healing processes (Fig. 2C).¹⁹² One example of antibacterial self-

assembled wound dressing studies is a synthetic polymeric hydrogel (oxadiazole-group-decorated quaternary ammonium salts (QAS)-conjugated poly(ϵ -caprolactone)-poly(ethylene glycol)-poly(ϵ -capro-lactone; PCEC-QAS) created by Liu *et al.*, especially for healing wounds infected with Gram-negative and Gram-positive bacteria. Methicillin-resistant *S. aureus*-infected skin wound on mouse was recovered successfully 12 days after hydrogel sealing of wound with PCEC-QAS.¹⁹³

3.5. Composite nanoparticles

Researchers have shown that a healthy wound healing can be achieved with a proper and multifunctional wound dressing. Although there are some certain criteria for a hydrogel wound patch, for different stages of wound healing process, different properties are required for a healthy healing.¹⁹⁴ To achieve a multifunction or a time-dependent functionality, the advantages of different materials can be used. Also, for more serious skin injuries like skin ulcers and skin burns, more effective wound dressings are needed. The advanced functions can be achieved by composite NPs incorporated in hydrogels as the hydrogels are typically used as a physical isolation and provide a moist environment.¹¹ These functional modifications are performed to gain the patches certain properties that can be

Table 1 Various nanoparticle loaded hydrogel materials used for wound healing

Types of hydrogels	Nanomaterial used	Dosages/exposure to wound area	Advantages	Applications	References
Guar gum hydrogels	Silver NPs	16 days	Boost up the proliferation, migration, and collagen production of human dermal fibroblasts	Antibacterial agent	220
Calcium alginate hydrogel	Chitosan NPs	MBC of 100 $\mu\text{g mL}^{-1}$	Induced skin wound healing and re-epithelialization by promoting the secretion of IL-6 in vascular endothelial cell	Antibacterial agent against <i>E. coli</i> and <i>S. aureus</i>	227
Poly ethylene glycol and cationic poly allyl amine hydrochloride hydrogel	Gold NPs	21 days	Enhanced skin re-epithelization and collagen deposition	Antibacterial agent against <i>S. aureus</i> and <i>P. aeruginosa</i>	228
Polycaprolactone and gelatin scaffold	Chitosan NPs	14 days	Promoted cell attachment and proliferation	Suitable scaffold for epidermis engineering and regenerative medicine	229
Carboxymethylcellulose hydrogel	Silver NPs	50 ppm	Maintains moist wound environment and facilitate early wound healing	Suitable for the treatment of deep infected wounds and antibacterial agent against methicillin resistant <i>S. aureus</i>	230
Cellulose hydrogel	Silver NPs	—	High cytocompatibility and better antioxidant properties	Suitable for moist wound dressing, antimicrobial agent against <i>S. aureus</i> , <i>P. aeruginosa</i> , and <i>C. auris</i>	231
Pullulan microneedle patch	Chitosan/fucoidan NPs	7 days	Helps to restore the collagen deposition by accelerated cell proliferation, granulation, and reduced pro-inflammatory cytokines	Smart and combined therapy for high-quality wound healing	232
Chitosan hydrogel	Silver NPs	250 ppm	Biodegradable porous hydrogels showed fast wound healing with no scar marks	Effective for diabetic patients and chronic burn wounds and antimicrobial agent against <i>S. aureus</i> , and <i>E. coli</i>	233
Gelatine hydrogel	Silver NPs	MIC of 63 $\mu\text{g mL}^{-1}$	Suitable as a vehicle for wound drug delivery due to its better physical properties	Antibacterial and anti-biofilm agent against <i>S. aureus</i> , <i>B. subtilis</i> , <i>P. aeruginosa</i> and <i>E. coli</i>	234
Collagen/chitosan scaffolds	Silver NPs	10 ppm	Modulate local inflammatory responses and promote	Ideal dermal substitute for	235

Types of hydrogels	Nanomaterial used	Dosages/exposure to wound area	Advantages	Applications	References
Poloxamer 407-based polymeric hydrogel	Polyurethane NPs	10 days	fibroblast migration by interacting with macrophages and fibroblasts Boost up the drug retention time in the tumor tissue	wound regeneration Effective against glioblastoma multiforme	236
Polymeric hydrogel	Simvastatin polymeric nanoparticles	11 days	Induced epithelialization, collagen fiber formation, and growth of hair follicle	Suitable for the topical wound healing	237
Cell loaded nanofibrous hydrogel	Glass–ceramic nanoparticles	21 days	Promoted cell attachment and proliferation, angiogenesis, collagen formation, regeneration of the sebaceous glands and hair follicles	Antibacterial agent	226
Gelatin collagen bioactive glass nanocomposite	Bioactive glass nanoparticles	14 days	Triggers expression of VEGF and angiogenesis	Suitable for the myocardial tissue engineering	238
Thiolated hyaluronic acid/silk fibroin dual-network hydrogel	Bioglass nanoparticles	14 days	Stimulate the migration of both fibroblasts and human umbilical vein endothelial cells	Suitable for the wound healing	239
Chitosan hydrogel	Nano bioglass	—	Cytocompatible and induce rapid blood clotting	Bleeding controlling agent	240
Chitosan/silk fibroin/glycerophosphate hydrogel	Bioactive glass nanoparticles	8 weeks	Induces osteogenesis and angiogenesis	Suitable for bone regeneration	241
Polymeric hydrogel	Eudragit nanoparticles	13 days	Acts as an efficient free radical scavenger	Promising for diabetic wound dressing	242
Gelatin based hydrogel	Asiaticoside polymeric nanoparticles	—	Improved collagen biosynthesis	Promising wound dressing	243
Polyvinyl alcohol nanofiber based hydrogel	Chitosan nanoparticles	—	Cytocompatible and shows continuous and slow release of drugs	Antibacterial agent	244
Dextran based hydrogel	Cerium oxide nanoparticle	—	Prolonged drug release, accelerated cell migration, <i>in vivo</i> anti-inflammatory activity	Ideal wound dressing	245
Poly(<i>N</i> -isopropylacrylamide) (PNIPAM) hydrogel	Silk fibroin-sodium alginate nanoparticles	20 days	Induces proliferation and growth of the fibroblast cells	Promising wound dressing	246
Silica-collagen type I nanocomposite hydrogel	Gentamicin and rifamicin, encapsulate silica nanoparticles	37 mg mL ⁻¹	Shows prolonged antibacterial activity against <i>Pseudomonas aeruginosa</i> and <i>Staphylococcus aureus</i>	Anti-bacterial wound dressing	104
Chitosan/gelatin hydrogel	Calcium phosphate nanoparticles	—	Modulates the porosity, swelling rate and mechanical strength as well as hMSC proliferation of bone scaffolds	Bone tissue engineering	128
Gelatin hydrogel	Titanium dioxide and zinc oxide nanoparticles	—	Exhibits adhesive effects between hydrogels, hydrogel/polymer, and tissues promoting wound closure and healing	Effective antimicrobial tissue adhesive	141
Carboxymethyl cellulose hydrogels	Magnesium hydroxide nanoparticles	—	Shows biocompatibility, hemocompatibility and the		149

Table 1 (Contd.)

Types of hydrogels	Nanomaterial used	Dosages/exposure to wound area	Advantages	Applications	References
Chitosan/sodium alginate/polyacrylamide hydrogel	Magnesium hydroxide nanoparticles	—	high antibacterial activity against <i>P. aeruginosa</i> biofilm formation Shows mechanical properties, high biocompatibility, improved broad-spectrum antibacterial activity and enhances <i>in vivo</i> wound healing process in a skin defect rat model	Potential wound dressing Next-generation wound dressing	150
Chitosan hydrogel	Titanium dioxide/aluminum oxide nanoparticles	—	Decreases total bacterial count, the expression of inflammatory genes, and increases the expression of proliferative genes, fibroblast, and collagen	Promising wound-healing material	153
Poly-(polyethyleneglycol citrate-co-N-isopropylacrylamide) hydrogel	Copper metal organic framework nanoparticles	—	Enhances dermal cell migration <i>in vitro</i> and wound closure rates along with angiogenesis, collagen deposition, and re-epithelialization, <i>in vivo</i>	Promising innovative dressing for the treatment of chronic wounds	156
3-(Trimethoxysilyl)propyl methacrylate hydrogel	Mesoporous silica (mSiO ₂) modified CuS nanoparticles	—	Stimulates fibroblast proliferation, angiogenesis and skin tissue regeneration as well as antibacterial effect	Skin tissue engineering and antimicrobial wound dressing	157
Gelatin methacryloyl hydrogel	Cerium oxide nanoparticles	—	Shows free radical scavenging activity, <i>in vitro</i> cell proliferation, and <i>in vivo</i> diabetic wound healing activity	Promising wound dressing for treating diabetic wounds	159
Polyvinyl alcohol/chitosan hydrogel	Cerium oxide nanoparticle	5 days	Shows antibacterial activity and healthy human dermal fibroblast viability	Robust wound dressing agent	161

listed but not limited to antibacterial property, adhesion, mechanical strength, hemostasis, antioxidant/anti-inflammatory, controlled delivery, self-healing, stimulus response, and conductivity.

In the previous sections, the effect of incorporating different types of NPs in hydrogels as wound dressings were discussed and the effect of each type of nanoparticle incorporation to a hydrogel wound patch system were presented. Here, we will also discuss the use of composite NPs in hydrogels that are developed for wound patches. The use of composite NPs can enhance the effect and/or has multifunction for serious skin damages or fastened healing without any damage or abnormality on the skin tissue.

Avoiding the bacterial inflammation, causing an improper deposition of collagen and delaying the wound repair is one of the most crucial aspects for developing a wound patch.¹⁹⁵ Especially for antibiotic resistant bacteria, different

antibacterial strategies must be followed. The use of inorganic metals such as silver, gold and zinc in composite NPs has been widely studied for its contribution to create antibacterial hydrogels. Among the inorganic metals, Ag NPs are the most widely used.¹⁹⁶ Aggregation is a challenge for such particles, thus hydrogels with composite NPs containing Ag are favourable.^{197,198} Another strategy is to use ceramic NPs such as ZnO,¹⁹⁹ and graphene oxide²⁰⁰ for antibacterial patches. Multifunctional antibacterial hydrogel wound patches can be fabricated by using composite NPs composed of oxides or inorganic metal NPs.²⁰¹ In a study by Fan and his coworkers,²⁰² Ag and graphene nanocomposite in polyacrylic acid and *N,N'*-methylene bisacrylamide hydrogels were fabricated to obtain antibacterial and high mechanical strength patches with accelerated wound healing.²⁰² They reported a high swelling ratio despite its enhanced tensile strength and elongation at break of hydrogel due to the use of graphene and antibacterial effect against both

Gram-positive and Gram-negative bacteria and a full-thickness skin wound healing was achieved. In another study, zinc-doped bioactive glass NPs incorporated in succinyl chitosan/oxidized alginate hydrogel was developed as an antibacterial wound dressing, which promotes the enrichment of fibroblasts, production of vascular endothelial growth factor and fibroblast growth factor 2.²⁰³ Also, the incorporation of zinc-doped bioactive glass NPs has significantly enhanced the release of angiogenic factors from the cells at the wound area of rats, which fulfils the multifunction purpose of the composite nanoparticle embedded hydrogel.

Another strategy for achieving antibacterial wound dressings is to use light-assisted antibacterial therapy that is locally raising the temperature to achieve the mortality of bacteria, which is also effective for drug resisted bacteria and produce less side effects.^{204,205} This technique can also be used to fabricate hydrogels containing composite NPs that can show photothermal effect. It has been shown that polyvinyl alcohol hydrogel was incorporated with reduced graphene oxide/MoS₂/Ag₃PO₄ nanocomposite particles to obtain efficient sterilization of the wound area under light irradiation.²⁰⁶ The antibacterial effect of Ag⁺ was enhanced with the ability to raise the local temperature with NIR illumination with the use of graphene oxide-based nanomaterials and MoS₂. Reduced graphene oxide further enhanced the mechanical property and swelling ratio of the hydrogel. The efficiency of *in vitro* and *in vivo* antibacterial activity of the reduced graphene oxide/MoS₂/Ag₃PO₄ PVA hydrogel was reported with no abnormalities in major organs in rats during the wound healing process.

Apart from achieving multifunctioning wound dressings, broad spectrum of antibacterial performance can also be achieved by incorporating composite NPs into hydrogel wound dressings. It has been reported that multiple targeting approaches were employed to achieve efficient antibacterial activity with a reduced risk of resistance.²⁰⁷ ZnO impregnated mesoporous silica NPs were used in carboxymethyl cellulose hydrogel and dual antibacterial effect of a broad-spectrum antibiotic tetracycline, which was loaded in mesoporous silica NPs and Zn²⁺, was achieved. The results proved that this composite nanoparticle structure effectively enhanced the antibacterial property with a wider inhibition zone against *E. coli*. This study also shows that composite NPs can also be used to efficiently develop a hydrogel wound patch with a drug release system.

Another strategy to overcome the increase of the drug-resistant microorganisms due to the over usage of antibiotics is to mimic the property of natural enzymes to generate ROS for disinfection by constructing artificial nanozymes.^{208,209} This artificial nanozymes can catalyze a low concentration of H₂O₂ into ·OH, which destroys the bacterial membrane *via* oxidation.^{210,211} Iron oxide,²¹² V₂O₅,²¹³ and graphene quantum dots²¹⁴ can be used as artificial enzyme catalysts to have antibacterial performance. However, the low efficiency of the nanozymes is still a challenge for effective antibacterial application. The use of composite NPs can enhance the efficiency of the nanozymes, as well as the multifunctional nanocomposites can be more beneficial. For example, in a study, Au nanoparticle with its

superb glucose oxidase-like activity was combined with Pt NPs that can convert H₂O₂ into O₂ was used to obtain a synergistic effect in an oxidized hyaluronic acid/carboxymethyl chitosan hydrogel.²¹⁵ The results showed that the developed wound dressing was antibacterial, reduced blood glucose, alleviated the oxidative stress and the supply of oxygen due to the glucose oxidase-like and catalase-like activity of Au/Pt alloy nanoparticle, also accelerating the wound healing *in vivo*. In another study tannic acid-chelated Fe-decorated MoS₂ nanosheets were incorporated in polyvinylalcohol, dextran and borax hydrogel and due to the peroxidase-like activity of MoS₂ and catalase-like activity tannic acid-chelated Fe, high and affective disinfection, and supply of O₂ was achieved.²¹⁶ Also, photothermal therapy was also integrated to the healing *via* tannic acid-chelated Fe. As a result, antibacterial, anti-inflammatory, adhesive, self-healing multifunctional hydrogel was developed for wound healing applications.

Recently, injectable and *in situ* forming hydrogels have emerged as a promising candidate for wound patches due to its advantage for fabricating different-shaped patches depending on the wound area.²¹⁷ It has been shown that an irreversible gelation of poly(*N*-isopropylacrylamide-*co*-*n*-butyl acrylate)-poly(ethylene glycol)-poly(*N*-isopropylacrylamide-*co*-*n*-butyl acrylate) copolymer *in situ* forming hydrogel containing silver NPs-decorated reduced graphene oxide nanosheets (Ag@rGO) was developed as a potential wound dressing. It was reported that the incorporation of Ag@rGO improved the stability and provides the irreversible gelation as well as significantly enhance the wound healing of methicillin-resistant *S. aureus*-infected wound.

4. Nanoparticle-loaded hydrogels for wound healing

Skin, being a 1st-line of defence of the human body, plays a vital role in regulating body temperature, shielding the human body from external injuries or pathogens, and is most likely to receive injuries. The skin wound is one of the most common clinical cases; hence it is of utmost necessity to develop an effective wound dressing. Wound dressings cover up the peri-wound area to provide a suitable wound-healing environment and prevent tissue dehydration. Conventional dressing systems are cheaper and easy to use but cannot provide a suitable wound-healing environment. Ideal dressing platforms should be biocompatible and have the ability to retain moisture with better mechanical strength.²¹⁸ A new wound-dressing approach has emerged in the current hunt for effective wound dressings, using both drugs and various innovative biomaterials to optimize and promote wound healing.²¹⁹ Researchers suggested that nanoparticle-loaded hydrogels for wound healing can be a better alternative to traditional dressing (Table 1). Hydrogels are three-dimensional with vigorous hydrophilic networks and can mimic the skin's ECM structure. Along with this, hydrogels have some inherent properties like better absorption and retention of water, biocompatible, and biodegradability to promote the healing process. Modern-day, wound dressing

systems focuses on the natural polymer (*e.g.*, chitosan, gelatin, collagen, cellulose, hyaluronic acid, *etc.*) hydrogel dressings over synthetic polymers because of their excellent biodegradability and biocompatibility and the ability to improve the microenvironment of the wound and promote healing at different stages.²²⁰ Nanomaterials in hydrogels have significantly enhanced mechanical strength by forming electrostatic interactions, hydrophobic interactions, hydrogen bonds, covalent bonds, *etc.*²²¹ NPs, mainly metal-based NPs (*e.g.*, silver, gold, copper), metal oxide NPs (*e.g.*, zinc oxide, titanium oxide, cerium oxide), polymer (*e.g.*, polyurethane, poly(lactic-glycolic acid), *etc.*) and glass-ceramic nanoparticles are exploited for wound healing. A study of nanogel based wound healing, Zhao and co-workers developed a genetically engineered polypeptide nanogel loaded with silver NPs as a wound healing as well as an antibacterial agent.²²² An earlier study suggested that cerium-doped biotype Linde type a zeolite-based NPs loaded chitosan hydrogel have the ability to healing the diabetic wound by eliminated mitochondrial ROS and promoted the angiogenesis.²²³ Similarly, advanced bioceramics and polymer based hydrogel play an integral role in wound healing process. Additionally, these nanoparticles showed antibacterial and antitumoral activity along with the enhanced osteogenesis and angiogenesis.^{224,225} Sharifi and co-workers developed a skin substitute in the form of silver-doped bioactive glass-ceramic nanoparticles-based embryonic fibroblast cell loaded hydrogel. This substitute could enhance the cell attachment, proliferation and angiogenesis.²²⁶

5. Ethical aspects

The emergence of the concept of nanomedicine is nearly 35 years ago and the technological developments in this area raised ethical issues concerning the use of nanomaterials due to the concept of “nanotoxicity”. As the nanomaterials exhibit different properties compared to their bulk counterparts, new knowledge, and research are needed for the use of each nanoparticle, especially in medicine. Especially due to the increase in the surface area to volume ratio, nanomaterials have enhanced reactivity both *in vitro* and *in vivo* which brings the necessity to a serious tracing.^{247,248} Despite the various advantages of using NPs as a part of therapy/healing, there is an increased risk of cyto- and/or genotoxicity. This risk is also dependent on the size, shape, and concentration of the NPs.^{249,250} As the material type, size, and route of exposure change, the risks can also be changed. Therefore, one must consider every situation and material separately.²⁵¹ Also, the accumulation of nanomaterials in the body can have its own potential toxic effects.²⁵² While investigating the benefits and research areas of NPs, it is an ethical response to point out the safety issues regarding nanomedicine products before being used in clinical trials.²⁵³ It is stated that the ethical issues about using NPs in medicine, including patient's rights, safety, and clinical trials, are also valid for other medical science and technologies. Knowing that every medication can have the risk of causing a side effect, deciding whether a technology is proven to be effective and safe can have some uncertainties. Also, it is a matter of fact how

much risk can be taken by the patients to accept new technology.²⁵⁴ If the potential risks of human exposure to nanomaterials can be stated certainly, scientists can work on risk minimization more effectively.²⁵⁵

6. Conclusions

Four overlapping and interdependent phases make up the well-organized process of wound healing where intricate cellular and molecular mechanisms regulate these phases. However, these stages occur naturally, but distinctive dressing strategies may improve and speed it up. Dressings have evolved in recent years with new options, such as polymer blends and nanotechnology tools, to produce better materials while ensuring an ideal climate for wound healing. The current review has covered the various wound healing techniques in great detail and shown both the benefits and pitfalls of using nanomaterials in hydrogel wound patches. In addition to strengthening the mechanical characteristics, water solubility, and cell adhesion, nanotechnology can also load different particles with specialized biological functions or antibacterial activities in the hydrogels to accomplish long-term and slow drug delivery. Moreover, it shows a more effective curative impact than traditional topical medications. Additionally, a lesser amount of medications can function better due to the huge surface area of the NPs, which also somewhat reduces its toxicity. Nanomaterial-enhanced custom wound dressings have enormous promise for customised wound treatment. To achieve minimal resistance and rapid wound healing, one should be aware of the major difficulties linked to nanomaterial wound wraps and how they interact with the wound. To comply with international health norms, manufacturing expenses should be decreased overall. As a result, the potential applications of hydrogels-NPs composites amalgamation are endless and should be further investigated in future studies.

The commercialization of nanoparticle-loaded hydrogels for wound healing has emerged as a promising field with significant potential for clinical applications. Silver, zinc oxide, or gold nanoparticles have been incorporated into these advanced hydrogel formulations, which have demonstrated impressive therapeutic properties facilitating healing of wounds. For instance, commercially available products like Nanomedic's SpinCare®,²⁵⁶ Systagenix's Acticoat™,²⁵⁷ and Mölnlycke's Mepilex® Ag²⁵⁸ utilize nanoparticle-decorated wound patches with antimicrobial activity, accelerated wound closure, and enhanced tissue regeneration. Commercial products containing nanoparticles have earned the attention of researchers, clinicians, and industry stakeholders, which has further accelerated the commercialization of nanoparticle-loaded hydrogels.²⁵⁹ The successful outcomes reported in studies evaluating the efficacy of silver nanoparticle-loaded hydrogels in treating chronic wounds²⁵⁶ and the accelerated wound healing capabilities demonstrated by zinc oxide nanoparticle-loaded hydrogels²⁵⁹ provide strong evidence for their commercial viability. Moreover, the biocompatibility and ease of synthesis of these hydrogel systems contribute towards their attractiveness for commercialization. The availability of commercial products

and their prospects are poised to increase as ongoing research continues to reveal new insights and refine the properties of nanoparticle-loaded hydrogels, ultimately benefiting patients and contributing to the advancement of wound healing therapies in the future.

Author contributions

PD, MHC, SA and AKM: conceptualization. PD, RM, AKM, MHC and OLF: funding acquisition. SA, OLF and AKM: investigation. AKM: project administration. SA, AKM: supervision. MLRM, OLF and MHC: visualization. PD, MC, MU, SS, CS, EAK, SK, ENK, ST, FB, RM and PR: writing – original draft. MHC, OLF, SA and AKM: writing – review & editing.

Conflicts of interest

There are no conflicts to declare.

Acknowledgements

P. D. was provided with an independent PhD fellowship for financial assistance (UGC-JRF; NTA Ref. No. 201610181190). R. M. was provided DST-INSPIRE PhD Fellowship (DST-INSPIRE-SRF; INSPIRE Code-IF190457). A. K. M. would like to acknowledge DST-SERB (E. E. Q./2021/000058) for financial assistance. This work was supported by grants from Conselho Nacional de Desenvolvimento e Tecnológico (CNPq), Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES), Universidade Federal de Mato Grosso do Sul (UFMS), Fundação de Apoio à Pesquisa do Distrito Federal (FAPDF) and Fundação de Apoio ao Desenvolvimento do Ensino, Ciência e Tecnologia do Estado de Mato Grosso do Sul (FUNDECT), Brazil.
