Reusable nano-catalyzed green protocols for the synthesis of quinoxalines: an overview

Rangappa S. Keri, ^a Dinesh Reddy,^a Srinivasa Budagumpi ^a
and Vinayak Adimule ^b

Heterocyclic compounds are very widely distributed in nature and are essential for life activities. They play a vital role in the metabolism of all living cells, for example, vitamins and co-enzyme precursors thiamine, riboflavin etc. Quinoxalines are a class of N-heterocycles that are present in a variety of natural and synthetic compounds. The distinct pharmacological activities of quinoxalines have attracted medicinal chemists considerably over the past few decades. Quinoxaline-based compounds possess extensive potential applications as medicinal drugs, presently; more than fifteen drugs are available for the treatment of different diseases. Diverse synthetic protocols have been developed via a one-pot approach using efficient catalysts, reagents, and nano-composites/nanocatalysts etc. But the use of homogeneous and transition metal-based catalysts suffers some demerits such as low atom economy, recovery of catalysts, harsh reaction conditions, extended reaction period, expensive catalysts, the formation of by-products, and unsatisfactory yield of products as well as toxic solvents. These drawbacks have shifted the attention of chemists/researchers to develop green and efficient protocols for synthesizing quinoxaline derivatives. In this context, many efficient methods have been developed for the synthesis of quinoxalines using nanocatalysts or nanostructures. In this review, we have summarized the recent progress (till 2023) in the nano-catalyzed synthesis of quinoxalines using condensation of *o*-phenylenediamine with diketone/ other reagents with plausible mechanistic details. With this review, we hope that some more efficient ways of synthesizing quinoxalines can be developed by synthetic chemists.

Dr Rangappa Keri is currently working as an Associate Professor at Jain University, Bangalore, India. Before joining Jain University, he did his post-doctoral work at Instituto Superior Técnico, Universidade de Lisboa, Lisboa, Portugal and Kyung Hee University, Seoul, South Korea. His research interest concern Organic and Medicinal chemistry. Especially, development of new drugs

including acetyl acetylcholinesterase (AChE) inhibitors, anti-cancer, neuroprotective agents and anti-virals by organic synthesis. Also, development of organometal and metalloorgano-catalyzed enantioselective methods for the synthesis of heterocyclic scaffolds.

Dr Reddy Dinesh obtained his B.Sc. in 2004, and M.Sc. in 2006, from the Karnatak University, Dharwad. In 2007, he worked as Junior Scientist – R & D at Sequent Scientific Ltd, Mangalore. He enrolled for PhD in Chemistry in 2010, under the supervision of Prof. K. M. Hosamani and obtained his PhD degree in 2016. He joined CNMS, Jain (Deemed-to-be University) in 2017 and is

currently working as Scientist D. A major thrust of his current research is the design and invention of new annulations strategies for the synthesis of new lead drug candidates.

Fig. 1 Numbering system in quinoxalines.

1 Introduction

Heterocyclic compounds are one of the hot/vast research topics for organic/medicinal chemists. Heterocycles play an important role in the field of drug discovery, biochemistry, materials chemistry, and other areas of science.¹ The majority of heterocyclic compounds found in nature contain nitrogen, making them the richest class of compounds compared to those containing oxygen or sulfur.² Among nitrogen-containing heterocycles, quinoxalines (3) are considered a privileged structure in medicinal chemistry because of their broad pharmacological/biological activity. Quinoxalines, also known as benzopyrazines (a benzodiazine family), have a bicyclic ring system made up of a benzene ring (1) fused with a pyrazine ring (2) (Fig. 1).

The compounds with a quinoxaline motif display an array of biological and pharmaceutical activities, such as antimicrobial,³ antitumor,⁴ antituberculosis,⁵ anti-HIV,⁶ anti-proliferative,⁷ anticancer,⁸ antileishmanial,⁹ anti-inflammatory,^{10,11} antiviral,¹² anti-protozoal,¹³ anthelmintic,¹⁴ antifungal,¹⁵ analgesic,¹⁶ antimalarial,¹⁷ antiepileptic,¹⁸ anti-convulsant,¹⁹ antiamebic,²⁰ anti-HCV,²¹ kinase inhibitors,²²

antidepressant²³ and *etc.* Quinoxaline cores also find prominent uses in agrochemicals as insecticides,²⁴ pesticides,²⁵ herbicides.²⁶ Other than biological/pharmacological applications, these structural moieties have also found applications in phosphorescence light emitting diodes, solar cells,²⁷ dyes,²⁸ organic semiconductors,²⁹ chemically controllable switches,³⁰ efficient electron luminescent material,³¹ cavitands,³² building blocks for the synthesis of anion receptor,³³ dehydroannulenes,³⁴ DNA cleaving agents³⁵ and also for the development of macrocyclic molecular receptors.^{36,37}

Some of the quinoxaline scaffolds are the parts of commercially marketed drugs to quote a few: brimonidine (4, used to treat open-angle glaucoma, ocular hypertension, and rosacea),³⁸ quinacillin (5, penicillin antibiotic which can reversibly deactivate beta-lactamase enzymes),³⁹ varenicline (6, agonist at nicotinic acetylcholine receptors used as an aid in smoking cessation),⁴⁰ echinomycin or levomycin/quinomycin A (7, peptide antibiotic),⁴¹ 6-cyano-7-nitroquinoxaline-2,3-dione (8, CNQX, AMPA/kainate receptor antagonist),⁴² YM90K (9, AMPA receptor antagonist),⁴³ NBQX (10, AMPA receptor antagonist),⁴⁴ XK469 (11, anti-tumor agent, effects by topoisomerase IIB inhibition),⁴⁵ chloroquinoxaline sulfonamide (12, CQS, NSC 339004, antineoplastic),⁴⁶ sulfaquinoxaline (13, veterinary medicine, to treat coccidiosis),⁴⁷ and olaquinox (14, growth stimulant) (Fig. 2).⁴⁸

Therefore, the synthesis of quinoxalines have received increasing attention from synthetic organic chemists and biologists. A variety of methods for the synthesis of quinoxaline derivatives have been developed/reported, for instance, the reaction between aryl-1,2-diamines and diethyl bromomalonate,⁴⁹ reductive cyclizations of 1,2-dicarbonyl compounds with 2-nitroanilines,⁵⁰ the reaction of aromatic 1,2-diamines with α -

Dr Srinivasa Budagumpi obtained his MSc degree in Inorganic Chemistry from Gulbarga University, Gulbarga, India, and PhD in Chemistry (with Prof. Vidyanand K. Revankar) from Karnatak University, Dharwad, India. He conducted post-doctoral research in homogeneous catalysis at Pusan National University, Busan, Republic of Korea, in bio-organometallic chemistry at the

Universiti Sains Malaysia, Penang, Malaysia, and in organometallics at the University Teknologi Malaysia, Johor, Malaysia. In 2014, he was appointed as an Assistant Professor in the Centre for Nano and Material Sciences at the Jain University, and currently, he is serving as an Associate Professor in the Centre. He is specialized in the fields of coordination and organometallic chemistry of late transition metals and their applications in bio-inorganic chemistry, homogeneous catalysis and electrochemical sensors.

Fifteen years of research experience as senior Scientist, associate research scientist in R&D organisations of TATA, Astra Zeneca India, Trans Chem Ltd. Expert in the area of Medicinal Chemistry, Material Chemistry and Sensors. Published more than 125 research articles, and books/book chapters in Scopus, Q-rated journals with high impact factor, attended and presented papers in National

and International Conferences, published books in Wiley, Trans-Tech etc., Chaired International and national conferences, Editorial Board Member, Life Member of many international societies/research institutions. Recognized Research Guide VTU, Belagavi. Research interest includes Nano Electronics, Material Chemistry, Sensors and Actuators, Bio Nanomaterials, Medicinal Chemistry.

alkynes with 1,2-diamines *via* key oxidation.^{58,59} The most simple and straightforward route for the synthesis of quinoxaline derivatives (**1**) is the direct condensation of 1,2-dicarbonyl compounds (**16**) and aryl 1,2-diamines (**15**) (Scheme 1). For this transformation, a variety of catalysts were used *viz.*, sulfamic acid,⁶⁰ oxalic acid,⁶¹ montmorillonite K-10,⁶² cerium(IV) ammonium nitrate,⁶³ Wells–Dawson hetero polyacid,⁶⁴ polyanilinesulfate salt,⁶⁵ gallium(III) triflate,⁶⁶ ionic liquid 1-*n*-butylimidazolium tetrafluoroborate,⁶⁷ molecular iodine,⁶⁸ bismuth(III) triflate,⁶⁹ indium chloride,⁷⁰ zirconium tetrakis(dodecyl sulfate),⁷¹ molybdophosphoric acid,⁷² zeolites,⁷³ graphite,⁷⁴ palladium,⁷⁵ copper,⁷⁶ iron exchanged⁷⁷ and, many more. Although, these aforementioned protocols unfold several remarkable features, the intrinsic difficulties arising due to the use of strong acids, costlier reagents, oxidants, elevated temperature, long reaction time, use of toxic solvents, the separation of catalyst from the reaction system, and reusability of homogeneous catalysts, inescapably add to the cost and even render its bleak commercial utility due to presence of these metal residues in the product stream.

To overcome these demerits, nanomaterials/nanocatalysts have emerged as better alternatives for several organic transformations as compared to conventional materials applicable to almost all types of catalytic organic transformations. In the last two decades, nanoparticles/nanocatalysts gained more attention to scientists to do more attractive innovations in diverse fields, including energy conversion and storage, chemical manufacturing, biological applications, semiconductors, photocatalysts, nanobots, and environmental technology. Among nanocatalysts, several forms such as nano-supported catalysts, graphene-based nanocatalysts, nano-mixed metal oxides, magnetic nanocatalysts, and core-shell nanocatalysts have been employed in catalytic applications.⁷⁸ Nanoparticle-supported catalysts/nanostructures can offer important advantages as compared to homogeneous transition metal systems. These include good reusability coupled with high activities, low preparation cost, great selectivity, high stability, excellent activity, and specificities in different chemistries based on their excelling properties (high surface areas, degenerated density of energy states, and plasmon). A few review articles have already been published revealing varied pharmacological and biological applications of quinoxaline and its derivatives^{79–81} and the application of transition metal for the synthesis of quinoxalines and also nano-catalysts with metal single-atom catalysts.^{82,83} These metal-based catalysts suffers some disadvantages like recovery and low yield. So, this review gives a comprehensive insight into the application of nanocatalysts for the synthesis of various substituted quinoxalines by the condensation of 1,2-dicarbonyl compounds and aryl 1,2-diamines and their plausible reaction mechanisms reported since 2000. The present review has been categorized depending on the types of nanocatalysts (like Fe, Ti, Cu, Co, Mn, Mo, Au, Ag, Zn, Zr, Si, Pd, and Ni-based nanocatalysts) used for the synthesis of quinoxaline. Representative examples of each category used for the synthesis of compounds bearing a quinoxaline core with the plausible mechanism of their synthetic assembly have been documented.

2 Synthesis of quinoxaline using nano-based catalyst

2.1. Iron-based nanocatalysts for the synthesis of quinoxalines

Iron-based nanoparticles have unique advantages such as high surface area, abundant, nontoxic, readily accessible, and retrievable which offer attractive supports for immobilizing various functional groups under mild conditions. Also, due to the magnetic properties of iron oxide, it provides a simpler work-up procedure in the separation stages with the use of an external magnet over filtration or centrifugation both in preparation and recovery.⁸⁴ Also, Fe NPs used in a wide range of applications like dechlorination, potential magnetic carriers, electrocatalysis, magnetic resonance imaging, remediation of aqueous metal contaminants, chromium removal, and in organic syntheses like imine synthesis, and various heterocyclic motifs.^{85,86} Fe-based nanomaterials were used for many organic transformations or heterocyclic synthesis.⁸⁷ Also, many Fe-based catalysts/materials were used for the synthesis of quinoxalines and are discussed in this section.

Sardarian *et al.* reported a Fe₃O₄@SiO₂/Schiff base complex of metal ions catalyzed the synthesis of quinoxalines using OPD and 1,2-diketones in aqueous media at room temperature (rt). The OPD (1 mmol) and benzil (1 mmol) were chosen as the model reaction to optimize the reaction conditions performed in the presence of 0.03 g Fe₃O₄@SiO₂/Schiff base/Co(II) nanocatalyst at rt in different solvents, such as acetonitrile, chloroform (CDCl₃), dichloromethane, ethyl acetate, water, ethanol, methanol, and different mixtures of EtOH/H₂O (3/1, v/v). The optimized results for the synthesis of 2,3-diphenyl quinoxaline (95% yield) were obtained using ethanol EtOH/H₂O at rt. The reaction was extended to various aromatic (electron-donating, electron/withdrawing) and aliphatic 1,2-diamines by reacting with benzil in the presence of Fe₃O₄@SiO₂/Schiff base/Co(II) (0.03 g) at rt to form various quinoxalines. The phenyl ring of 1,2-diamine with electron-donating groups (EDG), favored the formation of quinoxalines. The electron-withdrawing groups (EWG) such as –nitro, –benzoyl, and –chloro gave slightly lower yields. Especially substrate bearing –NO₂ group gave a lower yield even after longer reaction times. The aliphatic 1,2-diamines afforded the corresponding quinoxaline derivatives in slightly lower yields and longer reaction times. In the case of 1,2-diketone, EDG associated with aromatic decreased the product yields and the effect is contrary to EWG. The author examined the catalytical activity of different metal ions like Co(II), Mn(II), Ni(II), Cu(II), Cd(II), and Hg(II). Among various Lewis acids, Co(II) showed good catalytical activity and was found to be of the order Co(II) > Cu(II) > Ni(II) > Mn(II) > Cd(II) > Hg(II). Further, the used Fe₃O₄@SiO₂/Schiff base/Co(II) catalyst was recovered and reused five times with 97%, 96%, 96%, 95%, and 94% yield without loss of catalytical activity (Scheme 2).⁸⁸ In the same array, Zhang *et al.*, used the magnetic Fe₃O₄ nanoparticles for the synthesis of quinoxaline derivatives by condensation between 1,2-diamines and 1,2-dicarbonyls. The prepared nanoparticles were round in shape, with an average

Scheme 2 Synthesis of quinoxalines catalyzed by $\text{Fe}_3\text{O}_4@\text{SiO}_2/\text{Schiff base}$ complex of metal ions.Scheme 3 Synthesis of quinoxalines catalyzed by nano- Fe_3O_4 in aqueous media.

diameter of 20 nm. For the optimization of solvents, the reactions were carried out with various solvents such as toluene, dichloromethane, acetonitrile, ethyl acetate, ethanol, and water. The best conversion was observed when the reaction was performed in water at 10 mol% of Fe_3O_4 catalyst. A similar reaction condition was used for the synthesis of various quinoxalines, the catalyst was easily recoverable by applying an external magnet and was subsequently employed in the following five cycles without a noticeable decrease in the product yield (Scheme 3).⁸⁹

Sajjadifar *et al.* reported the preparation of $\text{Fe}_3\text{O}_4@\text{APTES}@$ isatin catalyst through immobilization of isatin sulfonic acid on silica-modified Fe_3O_4 nanoparticles that was shown to be an efficient heterogeneous catalyst for the synthesis

of quinoxaline derivatives using ethanol at rt. These synthesized nano particles have nearly spherical shape with sizes of about 16 nm. The reactions are optimized using different solvents, catalyst loading, and temperature through the reaction between OPD (1 mmol) and benzil (1 mmol) as the model reaction. The desired product was obtained in good yield using 25 mg of the catalyst and ethanol as a solvent. The catalyst was recycled and reused seven times without loss of activity, and it was indicated that $\text{Fe}_3\text{O}_4@\text{APTES}@$ isatin was a superior catalyst. The 1,2-dicarbonyl compounds including, benzil, phenanthrene-9,10-dione, and acenaphthylene-1,2-dione were reacted with OPD with electron-releasing/electron-withdrawing substituents to furnish the corresponding products (Scheme 4).⁹⁰ In continuation, the author prepared

Scheme 4 Application of $\text{Fe}_3\text{O}_4@\text{APTES}@\text{isatin}$ nanocatalyst for quinoxaline synthesis.Scheme 5 Synthesis of quinoxaline using $\text{Fe}_3\text{O}_4@\text{APTES}@\text{MOF-199}$ nanocatalyst.Scheme 6 Possible mechanism for synthesis of quinoxaline using $\text{Fe}_3\text{O}_4@\text{APTES}@\text{MOF-199}$ nanocatalyst.

Scheme 7 Synthesis of quinoxaline using Fe@SiCN catalyst.

Fe₃O₄@APTES@MOF-199 magnetic nanoparticles and characterized by Fourier transform infrared spectroscopy (FTIR), powder X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive X-ray (EDX), vibrating sample magnetometer (VSM) and thermogravimetric analysis (TGA). The particle size of the nanocatalyst is about 15–96 nm and the prepared catalyst was used for the synthesis of quinoxaline derivatives using ethanol as a solvent at rt. The author claimed the merits of the protocol are green catalyst, economic, easy workup, eco-friendly, non-toxic, and nanocatalyst with magnetic properties which can be easily recovered by a simple magnet, and can be reused several times (Scheme 5). The plausible mechanism of the reaction is proposed and the reaction pathway involves an initiation step, in that the carbonyl groups in diketone (16) are activated by nanocatalyst and further react with OPD (15) forms amino-1,2-diol (18) followed by dehydration to give quinoxalines (3) (Scheme 6).⁹¹

The replacement is an attractive and selectivity pattern for the development of novel coupling reactions. Using the same concept, Kempe *et al.*, have synthesized quinoxaline derivatives

from nitroarenes (19) and diketones applying silicon carbonitride-based iron (Fe@SiCN) as a catalyst. This catalyst is homogeneously distributed particles with an average particle size of 5 nm. The advantages of the protocols are robust, reusable, easy to synthesize, and easy to handle iron catalyst (Scheme 7).⁹² Malakooti and co-workers synthesized Fe(III)-Schiff base/SBA-15 heterogeneous nanocatalyst from Schiff base complex was encapsulated in SBA-15 mesoporous silica. From TEM image author confirmed this catalyst is supported complex shows retention of the hexagonal structure following grafting of the complex onto SBA-15. The catalyst is applied for the synthesis of pyridopyrazine and quinoxaline heterocycles. The catalyst showed good activity and high selectivity yield and was easily recycled taking advantage of the magnetic property (Scheme 8).⁹³ Azizi's group developed a magnetic nanoparticle with high multifunctional acidic groups by anchoring water-soluble 5-sulfosalicylic acid onto the surface silica-modified Fe₃O₄ (Fe₃O₄@SiO₂@5-SA) for the synthesis of quinoxaline derivatives from direct condensation of substituted 1,2-diamine with various 1,2-dicarbonyl in ethanol at rt with excellent yield.

Scheme 8 Synthesis of quinoxaline heterocycles catalyzed by Fe(III)-Schiff base/SBA-15 in water.

Scheme 9 Application of $\text{Fe}_3\text{O}_4@\text{SiO}_2/5\text{-SA}$ catalyst for the synthesis of quinoxalines.

The catalyst sizes of the MNPs were not precisely identical and showed core-shell morphology in various sizes, constructed by some nanoparticles and the size of the MNPs particles was well below 80 nm. After the reaction, the catalyst can be recovered by an external magnet and reused for five recycles without the effect of catalytical activity. Further, the author studied the effect of substitutes on diketone as well as for diamino compounds. For the aromatic 1,2-diketones with EWG or EDG, no notable difference in yields and reaction time was observed. In the case of 1,2-diamino benzenes, the EWG (like $-\text{NO}_2$), deactivated the aromatic ring and gave the product in moderate yields at prolonged reaction time. But it is the opposite for the EDGs, which were found to improve the rate of reaction and furnished quinoxaline derivatives in excellent yields (Scheme 9).⁹⁴

Javidi *et al.* explored the activity of $\text{Fe}_3\text{O}_4@\text{SiO}_2$ -imidazole-PMA magnetic porous nanosphere for the synthesis of quinoxaline derivatives. The prepared nanoparticles have spherical shapes with approximately 50 nm diameters and the size distribution of these is centered at a value of 55 nm. The author observed the electronic effect of the substrate affects the yield of the products. The EDGs at the phenyl ring of amine favored the formation of the product. Whereas, amine with EWGs such as $-\text{nitro}$, $-\text{benzoyl}$, and $-\text{chloro}$, gave slightly lower yields. The aromatic ketone with EDG decreased the product yields and the effect is contrary to EWG. After the completion of the reaction, the magnetic catalyst can be easily separated by the external magnetic field and reused for six times without loss of efficiency. The merits of the protocol are short reaction times, nanocatalyst stability, mild reaction conditions, excellent

Scheme 10 $\text{Fe}_3\text{O}_4@\text{SiO}_2$ -imidazole-PMA magnetic porous nanosphere catalyzed synthesis of quinoxaline.

Scheme 11 Synthesis of quinoxaline using nano-kaoline/BF₃/Fe₃O₄ nano-catalyst.

yields, simple work-up procedure, and involvement of an efficient and recyclable catalyst (Scheme 10).⁹⁵ Mirjalili *et al.* studied the catalytic activity of nano-kaoline/BF₃/Fe₃O₄ nano-catalyst, used for quinoxaline preparation *via* condensation of 1,2-phenylene diamines and 1,2-diketones under grinding conditions. Kaoline is a clay mineral consisting of hydrated aluminum silicate and the particle size of the catalyst below 25 nm. The author claimed the advantages of the methodologies such as being solvent-free, good to excellent yields, easy work-up; and using non-toxic, inexpensive, and reusable catalysts (Scheme 11).⁹⁶ Rangappa *et al.* used the heterogeneous nano-γ-Fe₂O₃-SO₃H catalysis for the synthesis of quinoxalines using OPDs with electronically diversified 1,2-diketones and α-bromoketones *via* simple cyclo-condensation reaction under solvent-free conditions. The OPDs with EDG afforded

quinoxalines in good yield when compared with OPDs with EWG. The α-bromoketone without substitution favored the formation of quinoxalines in higher yield compared to the substituted α-bromoketone. The catalyst was recovered and reused for five runs without any deactivation. The author proposed a mechanism, it involves the protonation of carbonyl groups of 1,2-diketone followed by cyclo-condensation with OPD (Schemes 12 and 13).⁹⁷

Farrokhi and co-worker synthesized inorganic-organic hybrid nanocomposite 1,4-piperazinediylbis(methylene) bisphosphonic acid (PBA) with starch-coated maghemite nanoparticles (SMNP) (PBA@SMNP) by supporting a bisphosphonic acid on starch-coated γ-Fe₂O₃ nanoparticles. These materials were characterized by IR, XRD, SEM, TEM, and VSM. The materials appeared as spherical or quasi-spherical shapes

Scheme 12 Synthesis of 2,3-diaryl/heteroaryl/2-aryl/heteroaryl quinoxalines using nano-γ-Fe₂O₃-SO₃H catalyst.

Scheme 13 Proposed mechanism for the formation of quinoxalines using nano- γ - Fe_2O_3 - SO_3H catalyst.

Scheme 14 Synthesis of quinoxalines over PBA@SMNP.

of PBA@SMNP nanocomposite particles, with an average diameter of 11 nm. The catalytic activity of this material was evaluated using 1,2-diamines with 1,2-dicarbonyls and aldehydes to get the desired benzimidazoles and quinoxalines respectively. The author concluded; the presence of Brønsted acid organocatalyst on the surface of maghemite nanoparticles assured their stability and has a considerable effect on their efficiency. The catalyst can be recovered using a magnet and no

deactivation occurred on the catalyst after it was reused for 5 runs (Scheme 14).⁹⁸ Borhade *et al.*, used a nanocrystalline 5% Fe/ZnO catalyst for the preparation of quinolones from OPDs and phenacyl bromides at rt. The nanomaterial is prepared from the hydrothermal method and characterized by XRD, SEM, EDAX, TEM, and SAED techniques. The TEM analysis reveals that the nanoparticles are hexagonal with several spherical-shaped crystallites and the average size of nanocrystallites is

Scheme 15 Synthesis of quinoxalines using 5% Fe/ZnO nano particles.

Scheme 16 Synthesis of various quinoxalines catalyzed by FeNPs.

around 62.3 nm. From the electronic substitution study, the phenacyl bromide with EDG furnishing gave corresponding quinoxaline, high yield with less time but it is reversed in the case of EWG substituents. After the recovery of the catalyst, it is stable and reusable even after five cycles without appreciable

loss in activity (Scheme 15).⁹⁹ Arde and co-workers synthesized amorphous iron nanoparticles (FeNPs) using an aqueous leave extract of *Boswellia serrata* plant and the FeNPs were stabilized *in situ* by the addition of aqueous extract of *Acacia concinna* as a bio-surfactant. These NPs were characterized using XRD, UV,

Scheme 17 Plausible mechanism for the synthesis of quinoxalines using by FeNPs.

EDX, SEM, TEM, and other techniques. These nanoparticles are amorphous in nature with particle size around 19 nm. The catalytic activity of these FeNPs was performed by the synthesis of quinoxalines using OPDs with electronically diversified benzils. The benzils without any substituent and substituents with EWGs gave the desired quinoxalines in a shorter time with good yield when compared with benzil with EDG, which took a long time. The mechanism of the reaction proceeds by oxidative addition of FeNPS on carbonyl oxygen of benzil followed by nucleophilic attack of lone pair of nitrogen of OPD on activated carbonyl carbon and the same process was followed for benzil to form a cyclic intermediate. The six-membered cyclic intermediate abstracts proton from solvent, leaving behind FeNPS to form a dihydroxy intermediate followed by dehydration to obtain the corresponding quinoxalines (Schemes 16 and 17).¹⁰⁰

2.2. Copper-based nanocatalysts for the synthesis of quinoxalines

Copper has a high boiling point, which makes it compatible with high-temperature and pressure chemical reactions, including microwave-assisted reactions, vapor-phase reactions, continuous flow reactions, and various organic transformations. Copper-based nanocatalysts have found many applications in nanotechnology, including catalytic organic transformations, electrocatalysis, and photocatalysis.^{101–103} Also, the copper-based nanocatalysts/nanomaterial is used for the synthesis of quinoxalines, and the same is discussed here. Bardajee and co-workers prepared Cu(II)-Schiff base/SBA-15 catalysts and characterized them from TEM, XRD, and

nitrogen adsorption/desorption isotherms. The morphology of the material showed a 2D-hexagonal array of uniform linear channels with the typical honeycomb. The catalyst exhibited lack of pore blocking or agglomeration of copper metal and the pore size can determine to be 8 nm for the catalyst. Further, this catalyst was utilized for the synthesis of quinoxaline and pyridopyrazine derivatives. The reactivity of diamines is generally dominated by electronic effects. The hetero-aromatic diamines showed less reactivity in comparison with aromatic or aliphatic diamines. The catalyst recovered after the completion of the reaction and reusability over six successive runs without the loss of activity. In the same array, the author synthesized the same quinoxaline derivatives using Cu(II)-DiAmSar/SBA-15. This material retaining of the cylindrical shape of the pores and the hexagonal arrays of uniform channels (Schemes 18 and 19).^{104,105} Nakhate and co-workers described the synthesis of quinoxaline derivatives from various terminal alkynes with OPDs by using copper alumina catalyst. Author used different mole ratios of $\text{Cu}^{2+}/\text{Al}^{3+}$, 2 : 1 (Cu-Al-1), 2.5 : 1 (Cu-Al-2) and 3 : 1 (Cu-Al-3) for this methodology. These materials are agglomerated particles and there is no significant change in morphology was observed for the different ratios of $\text{Cu}^{2+}/\text{Al}^{3+}$ (2, 2.5 and 3). Among these, Cu-Al-2 showed excellent activity at 60 °C in presence of K_2CO_3 . From substrate study, author concluded terminal alkynes with electron-deficient groups afforded excellent yields as compared to the electron-rich species. Also, present protocol works good with aliphatic alkynes such as hexyne and cyclohexyne. Where in case OPD, electron-rich group such as methyl, afforded a good yield but the strong electron-deficient group such as $-\text{NO}_2$ does not tolerate the

Scheme 18 Synthesis of quinoxalines derivatives in the presence of Cu(II)-Schiff base/SBA-15.

nanocrystalline copper(II) oxide. These CuO were characterized by XRD and transition electron microscopy (TEM) techniques. The average size of the obtained CuO particles is 5 nm and the mean value of surface area was 32.457 m² g⁻¹. The reactions were carried out at aqueous media and catalyst is recovered

Scheme 22 Synthesis of quinoxalines using g-C₃N₄/Cu₃TiO₄ (CNCT).

after the completion and reused up to four cycles without affecting the activity. In continuation, author used same catalyst and prepared various benzoheterocycles under ultrasonic irradiation. The advantages of the protocol are higher yields, short reaction times, and mild reaction conditions, with reusability of the catalyst (Scheme 21).^{107,108} Arunachalapandi and co-workers developed a heterogeneous g-C₃N₄/Cu₃TiO₄ (CNCT) catalyst for the preparation dihydro-quinazolinone and quinoxaline compounds from benzil, diamines, and aldehydes in ethanol under ultrasound with visible light irradiation. The synthesized CNCT nanocomposite was characterized by XRD, TEM, AFM, EDX, X-ray photoelectron spectroscopy, UV-vis diffuse

reflectance spectroscopy, Photoluminescence, BET, zeta potential, and thermogravimetric analysis. Through these analyses it was confirmed that material/catalyst is high crystalline nature, optical light-absorbing property, high surface area, and stability. The catalyst is sphere-like morphology and particle size is around 47 nm. Through these methods various quinoxalinone and quinoxaline derivatives were synthesized without the electronic affects. It was observed that sonication activates the catalyst surface and produces more amounts of active sites. The cavitation also reduces the activation energy barrier and gives the final products (Schemes 22 and 23).¹⁰⁹

Scheme 23 Plausible mechanism for the synthesis of quinoxalines using CNCT.

Scheme 24 Ni(II) ion loaded Y-type zeolite catalyzed synthesis of quinoxalines.

2.3. Nickel-based nanocatalysts for the synthesis of quinoxalines

Nickel-based catalysts are becoming very popular in organic synthesis and are used for the synthesis of a wide range of valuable organic compounds such as spiro and condensed indole derivatives, aromatic heterocycle, 5-substituted 1*H*-tetrazoles, quinolines, spirooxindoles, polyhydroquinolines, and sulfoxidation.¹¹⁰ Various Ni-based catalysts were used for the synthesis of quinoxalines and were discussed in this section. Mehdi and co-workers developed nanoporous Ni(II) ion-loaded Y-type zeolite (NNZ) material and applied it for the synthesis of quinoxalines, pyrido[2,3-*b*]pyrazines, and indolo[2,3-*b*]quinoxalines. The catalyst was identified with FT-IR, EDX, SEM, and BET analysis. The particle size was about 54–119 nm and the peak appeared in the region of 7.5 eV confirming the presence of nickel metal deposited on zeolite. The presence of EWG (–NO₂) substituent on the phenyl ring diamine, decreased the reaction yield, and substituted EDG (CH₃) was the contrary (Scheme 24).¹¹¹ Ajeet Kumar *et al.*, synthesized monodispersed Ni-nanoparticle (size around 14–18 nm) and further utilized material for the efficient preparation of quinoxaline using a number of 1,2-diamines were condensed with glyoxal using 10 mol% of Ni-nanoparticles at 25 °C under N₂ atmosphere. The OPD with the ED substituents the reaction was faster while EW substituents decreased the rate of the reaction. The Ni-

nanoparticles play a complex role in accelerating the dehydration step of a reaction and this promotes the formation of products. The Ni-nanoparticles will be recycled by separating them from the reaction mixture by mild centrifugation and used them up to six cycles, without a change in their catalytic activity (Scheme 25).¹¹²

2.4. Gold-based nanocatalysts for the synthesis of quinoxalines

The exploration of gold nanoparticles (Au-NPs) as catalysts has attracted tremendous attention in recent years in the context of developing environmentally friendly and sustainable routes to a myriad of important organic transformations. AuNPs of small size show excellent catalytic performance for many chemical reactions examples include the reduction of carbon–carbon triple bonds or of nitroarenes, aerobic oxidation of alcohols, and carbon–carbon bond formation.¹¹³ Also, these Au-nanoparticles are applied for the preparation of quinoxaline and its derivatives. Climent and co-workers synthesized gold nanoparticles supported by nanosized CeO₂ (Au/CeO₂) or hydrotalcite (Au/HT, cubic in shape) as catalysts and further used for the synthesis of quinoxaline derivatives by 1,2-propanediol and OPD under base-free conditions. The catalyst can be easily recovered and reused with a small loss of activity. The EWGs such as –nitro, –chloride, or –nitrile groups, are present,

Scheme 25 Synthesis of quinoxalines using Ni catalyst.

Scheme 26 One-pot synthesis of quinoxaline derivatives using Au/CeO₂.Scheme 27 Synthesis of benzimidazolquinoxaline using Au/CeO₂ catalyst.

and quinoxaline derivative yields are lower with respect to OPD. The reactant with ED substituents like methyl, $(-\text{CH}_2)_4$, or methoxy groups enhance the yield (Scheme 26).¹¹⁴ Further, the author extended the catalyst system for the synthesis of benzimidazolquinoxaline derivatives through the oxidative coupling of glycerol or glyceraldehyde with OPD derivatives. EWGs improved the selectivity of the benzimidazolquinoxaline compound. The catalyst could be easily recovered and reused with a small loss of activity thereby maintaining high selectivity (Scheme 27).¹¹⁵ Bhattacharya and co-workers developed 4-amino thiophenol self-assembled monolayer coated gold-nanoparticles (Au-NPs, size around 10 nm) and applied these NPs one-pot synthesis of quinoxalines *via in situ* oxidation of α -hydroxy ketones and subsequent condensation with aryl 1,2-diamines in water. The aryl α -hydroxy ketones with various substituents on the aromatic ring produced the desired oxidized product. The EWG on the aromatic ring increased the

yield when compared to EDG. The reusability of the catalyst was limited after a few cycles of oxidation due to agglomeration of the nanoparticles (Scheme 28).¹¹⁶

2.5. Silica-based nanocatalysts for the synthesis of quinoxalines

Silica nanoparticles (NPs) have aroused great attention thanks to their exclusive physicochemical properties as well as the ability to control and adjust them. These silica NPs have promising properties, such as chemical inertness, controlled porosity, high surface area, firm framework, nanometer size, and very good thermal, mechanical, and chemical stability, the metals nanoparticles coated by SiO₂ become one of the most important catalysts of these types used in different fields. Due to the specific physicochemical characteristics of various strategic materials such as platinum (Pt), cobalt (Co), copper (Cu),

Scheme 28 Syntheses of aryl 1,2-diketones and quinoxaline derivative using AuNPs.

Scheme 29 Syntheses of quinoxaline derivatives using SiO_2 nanoparticles.

palladium (Pd), and gold (Au), they are extensively utilized in many modification and synthetic strategies in modern organic synthesis, especially in catalytic activities.^{117,118} Hasaninejad and co-workers developed an efficient method for the synthesis of quinoxalines from the condensation of 1,2-diamines with 1,2-diketones by using silica nanoparticles-catalyzed under solvent-free conditions at rt and affording high yields of quinoxalines with short reaction times. The reactions were carried out with

different oxides (MgO, CaO, SiO_2 (60–120 mesh), and neutral Al_2O_3). The SiO_2 nanoparticles gave excellent results in order of yield and reaction time. Highly microporous solids such as silica NPs offer a wide range of active sites and often can be regenerated if deactivated during the reaction. The aryl 1,2-diamines with EDGs had no significant effect on the reaction, whereas EWGs decreased the yields and increased the reaction times. The 1,2-diketones with different substituents have

Scheme 30 The proposed mechanism for the synthesis of quinoxalines using silica NPs.

Scheme 31 Nano-BF₃·SiO₂ catalyzed the synthesis of quinoxalines.

Scheme 32 Synthesis of quinoxalines using tungstophosphoric acid immobilized on mesoporous silica nanoparticles (SNPX#WPA).

a negligible influence on the reaction yields. The presence of the reactive -OH groups on the surface of the silica NPs plays a major role in its catalytic activity. Based on this, the author proposed a plausible mechanism, the benzil is activated by the O-H group of silica NPs followed by the N-nucleophilic amine attack on the carbonyl to form intermediate **I** and subsequently form intermediate **II**. During this process, quinoxaline is produced due to dehydration. The catalyst can be recovered and reused up to fifteen times and after three cycles the slightly catalytic activity is decreased (Schemes 29 and 30).¹¹⁹ Mirjalili and co-workers have investigated nano-BF₃·SiO₂ as a green and reusable solid acid catalyst for the synthesis of 2,3-disubstituted quinoxalines *via* condensation of α -diketones and OPD. The nano-BF₃·SiO₂ is noncorrosive, eco-friendly, and reusable which has a gradual decline in activity. The reaction was carried out under solvent-free conditions at room temperature under sonication conditions (Scheme 31).¹²⁰

Sosa *et al.*, prepared an acid catalyst (nanostructure) composed of tungstophosphoric acid immobilized on mesoporous silica nanoparticles. The catalyst with the strong acid sites and specific surface area of 222 m² g⁻¹, mesopores centered at 8.6 and 37.0 nm, and an acidity of 194 mV. Further utilized this material, for the synthesis of quinoxaline and their derivatives by the condensation of 1,2-dicarbonyl compounds with aromatic 1,2-diamines in an aprotic organic solvent at low temperature. The presence of electron-attracting group in OPD,

such as a halogen increases the yield and reduces the time to form quinoxaline with respect to non-substituted OPD. This effect is more remarkable when the aromatic ring presents a heteroatom such as nitrogen. Moreover, the introduction of a methyl group at the *ortho* position, causes an increase in the yield. The substituents in the 1,2-ethanodione with the presence of both electron-attracting (fluorine) and electron-releasing (methyl) substituents causes a significant increase in yield of the quinoxaline. Author proposed the plausible mechanism, in the first step the dione is coordinated to the catalyst, followed by a nucleophilic attack in the carbonyl carbon by the 1,2-phenylenediamine amino groups. Then, the carbocation intermediate is obtained by dehydration and elimination of the protons to give the quinoxaline, and the catalyst is regenerated (Schemes 32 and 33).^{121,122} The silica-based nanosphere-graphene oxide (SiO₂-GO) hybrid was prepared by Shitre and co-workers. Further, this material was characterized by TEM, FTIR, EDS and XRD. The GO acted as a good supportive substrate for controlling the size and activity of SiO₂ nanospheres with their cooperation towards catalytic reactions. The SiO₂ nanospheres with monodispersed sizes are decorated homogeneously on GO nanosheets. Later, this catalytic system used for the synthesis of functionalized quinoxalines by the condensation of OPD with substituted phenacyl bromide/2-diketone at rt in the presence of acetonitrile as a solvent. The phenacyl bromide containing EW and ED groups did not affect

Scheme 33 Plausible mechanism for the synthesis of quinoxalines using tungstophosphoric acid immobilized on mesoporous silica nanoparticles (SNPX#WPA).

Scheme 34 Synthesis of quinoxalines using SiO₂-GO as a catalyst.

significantly on the product yield. The nanostructured SiO₂-GO hybrid can be easily recovered by a simple filtration method and reused further for a minimum of four cycles without losing considerable activity (Scheme 34).¹²³

2.6. Titanium dioxide (nano-TiO₂)-based nanocatalysts for the synthesis of quinoxalines

Titanium dioxide nanoparticles (nano-TiO₂) are one of the most interesting metal oxides because high activity, strong oxidizing

power, easy availability, non-toxicity, reusability, and long-term stability. The nano titanium dioxide is a versatile material for various kinds of industrial applications related to catalysis, photocatalysis for pollutant elimination photovoltaics, or sensors, paints, and organic synthesis.^{124,125} Alinezhad and co-workers synthesized TiO₂ nanoparticles by the sol-gel method using titanium tetra-isopropoxide, deionized water, ethanol and HNO₃ under ultrasonic irradiation. The NPs were round in shape, with an average diameter of 50 nm, and further the catalytic activity of nano-TiO₂ was examined by synthesizing

Scheme 35 TiO₂ catalyzed synthesis of quinoxalines.Scheme 36 Application of TiO₂-P₂₅-SO₄ for the synthesis of quinoxalines.

2,3-diphenyl quinoxaline using various 1,2-diketones with substituted OPDs. The substituted at the 4-position with EDGs in OPD, higher rates, and yields are observed than the ones bearing EWGs at that position. The catalyst was recovered and reused, it shows highly efficient after the fourth run.¹²⁶ Also, Mirjalili *et al.*, have developed the same catalytical system (TiO₂) for the preparation of quinoxaline derivatives (Scheme 35).¹²⁷ Krishnakumar and Swaminathan have prepared the sulfated TiO₂-P₂₅ (Degussa titania) (TiO₂-P₂₅-SO₄) by sol-gel method using H₂SO₄ and utilized this material for the synthesis of quinoxaline, dipyrrolypyridine derivatives and chalcones under microwave condition. The synthesized material was characterized by FT-IR, XRD, FE-SEM, EDS, HR-TEM, XPS, DRS and BET surface area measurements. These particles exhibit a cloud like structure and size in the range from 20 to 100 nm. The EDGs at the phenyl ring of 1,2-diamine favor the formation of product, while, EWGs such as -fluoro, -chloro, and -carboxy slightly decrease the product yields. The recovered catalyst can be used five times without any loss activity, and it was found to be 98% even at the fifth run (Scheme 36).¹²⁸

2.7. Zirconium-based nanocatalysts for the synthesis of quinoxalines

In recent years, zirconium-based nanoparticles have attracted much attention from scientists due to their specific optical and

electrical properties, and their potential applications in transparent and fuel cells, advanced ceramics, optical devices, catalysis, and sensors.^{129,130} Also, zirconium compounds have found an ever-increasing role in organic synthesis, as revealed by the extensive literature on zirconium compounds as catalysts or reagents in synthetic organic chemistry.¹³¹ In this section, we were discussed how these materials are used for the synthesis of quinoxalines. Jafarpour and co-workers used monoclinic zirconia nanoparticles as a heterogeneous catalyst for the synthesis of quinoxaline derivatives. This nanomaterial is characterized by spectroscopic methods and reveals the formation of monoclinic zirconia with spherical nanoparticles with 20–40 nm diameter from TEM analysis. Further, the author utilized this material for the preparation of quinoxalines. The condensation reaction of a diamine bearing a strong EWG or a dicarbonyl compound substituted with a strong EDG proceeded slowly. The nano ZrO₂ can be reusable till the five cycles without the effect of catalytical activity (Scheme 37).¹³² In the same array, the author used zirconium Schiff base complex immobilized on starch-coated maghemite nanoparticles (ZrOL₂@SMNP). The material is spherical in shape with an average size of 10–14 nm. The catalytical activity is performed by condensation of various 1,2-diamines and 1,2-dicarbonyls for the synthesis of quinoxalines and pyrido pyrazines. The diamine bearing a strongly EWG or a dicarbonyl compound

Scheme 37 The synthesis of quinoxalines using nano ZrO₂.Scheme 38 The ZrOL₂@SMNP catalyzed synthesis of quinoxalines. The black sphere surrounded by white layer represents starch-coated Fe₂O₃.

substituted with a strongly EDG proceeded slowly. The catalyst was recovered by decantation of the reaction mixture in the presence of an external magnet and reused it for up to four

cycles without loss of catalytical activity (Scheme 38).¹³³ Teimouri and co-workers used nano sulfated zirconia, nano-structured ZnO, nano-γ-alumina and nano-ZSM-5 zeolites as

Scheme 39 The synthesis of quinoxalines using nanosulfated zirconia, nano-structured ZnO, nano-γ-alumina and nano-ZSM-5 zeolites.

Scheme 40 Plausible mechanism for the synthesis of quinoxalines using catalysts (nanosulfated zirconia, nano-structured ZnO, nano- γ -alumina and nano-ZSM-5 zeolites).

the catalyst for the synthesis of different heterocycles like benzimidazoles, benzoxazoles, benzothiazoles, and quinoxalines. Among the four catalytical systems, the nano-sulfated zirconia exhibited greater activity. According to the author, this mechanism involves the coordination of a 1,2-dicarbonyl onto acid sites *via* an acid catalyst, followed by nucleophilic attack on a diketone and dehydration to form a carbocation intermediate and proton elimination to form quinoxalines (Schemes 39 and 40).¹³⁴

2.8. Cobalt-based nanocatalysts for the synthesis of quinoxalines

Cobalt or cobalt-supported catalysts are an important material system in the field of heterogeneous catalysis. Cobalt as a late 3d transition metal has a rich coordination and organometallic chemistry, which has been explored for synthetic and catalytic purposes.^{135,136} The cobalt NPs (Co-NPs) are used for the

synthesis of quinoxalines and are discussed in this section. Nitrogen-doped carbon-supported cobalt nanoparticles from various cobalt precursors and phenanthroline were prepared by Panja and co-workers. In addition to the synthesis of 2-methyl quinoxaline from OPD and dicarbonyl derivatives, cobalt materials were tested for their catalytic activity in coupling nitroarenes with benzyl alcohols to prepare imines. These materials disclosed the existence of CoO and Co₃O₄ which were uniformly dispersed over the N-doped carbon support and the average particle size of 17.53 nm and 18.2 nm. Among all the Co-catalysts, the Co-phen/C-800 showed superior results, and the electronic effect with a diol, having diphenyl or *tert*-butyl substitution lowers the yield of the desired product. The catalyst was recycled and used up to 8 cycles and this heterogeneous system did not lose its catalytic activity significantly (Scheme 41).¹³⁷ Sharma and co-workers synthesized Co₃O₄ nanocages decorated with nickel nanoparticles Ni@Co₃O₄, an

Scheme 41 The synthesis of quinoxalines using Co-phen/C-800.

Scheme 42 $\text{Ni}@\text{Co}_3\text{O}_4$ (Co_3O_4 nanocages decorated with nickel nanoparticles) for the synthesis of quinoxalines.

Scheme 43 The synthesis of quinoxalines using Co nanoparticle.

average size of about 65 nm. These cage materials have hollow architectures that can help in achieving high reactivity and intensifying their role in various important organic reactions. The catalytic system was applied for the synthesis of quinoxalines with numerous 1,2-diketones and 1,2-diamines. Substrates containing deactivating groups such as $-\text{Cl}$, $-\text{Br}$, *etc.* required a longer reaction time. Also, this methodology is useful with aliphatic 1,2-diketones, resulting in a good conversion percentage and exhibiting a high turnover number. The nanocomposite $\text{Ni}@\text{Co}_3\text{O}_4$ was reprocessed/recycled by simple centrifugation and used up to six times without any appreciable loss in its catalytic activity (Scheme 42).¹³⁸ The cobalt nanoparticles on mesoporous SBA-15 were synthesized by Rajabi and co-workers. Later this catalyst was applied for the preparation of quinoxalines from 1,2-diamines and 1,2-dicarbonyls under mild reaction conditions. The supported nanocatalyst exhibited excellent activity, stability and it could be reused at least ten times without any loss of catalytic activity (Scheme 43).¹³⁹

2.9. Molybdenum-based nanocatalysts for the synthesis of quinoxalines

The molybdenum-based nanomaterial/nanocatalysts are extremely important for industrial applications. Mo-based catalysts can be active and selective for many reactions. Hydrogenation of benzene, selective oxidation hydrogenation/

dehydrogenation, and cracking of hydrocarbons, are a few examples of the important applications of these catalysts.^{140,141} The Mo-based nanocatalysts were used for the synthesis of nitrogen-containing heterocycles like quinoxaline and the same was discussed in this section. The crystalline nanobelts of $\alpha\text{-MoO}_3$ nanomaterial were prepared by Jafarpour and co-workers. The material was characterized by XRD, FT-IR, Raman spectroscopy, HRTEM, SEM, and TPD (temperature-programmed desorption). From TEM analysis, it is confirmed, the nanobelt morphology of $\alpha\text{-MoO}_3$ ranged from 20–70 nm in width and 200–400 nm in length. Further, these $\alpha\text{-MoO}_3$ nanobelts were utilized as a heterogeneous catalyst for the synthesizing quinoxaline derivatives. The condensation reaction of a diamine bearing a strong EWG or a dicarbonyl compound substituted with a strong EDG proceeded slowly. The catalyst can be recovered after the reaction; it is separated by centrifuging followed by decantation. The isolated solid phase (nano-MoO_3) was then dried under reduced pressure and reused for five runs without any noticeable drop in the product yield and its catalytic activity. The main advantages of this methodology are environmentally friendly, cost-effective, and industrially important because of the catalyst reuse and the use of safe reaction media (Scheme 44).¹⁴² In the same array, the author used keplerate $\{\text{Mo}_{132}\}$ nanoball for the synthesis of quinoxaline derivatives. These clusters showed ball morphology with

Scheme 44 Nano-MoO₃ catalysed synthesis of quinoxalines.

Scheme 45 Synthesis of quinoxalines using keplerate {Mo132} nanoball.

sizes ranging between 5 and 25 nm. The condensation reaction of a diamine with a strong EWG, and a dicarbonyl compound substituted with a strong EDG, did not proceed quickly. The author proposed the plausible mechanism, the main role of the {Mo132} acts as a Lewis acidity of the plenty of Mo centers in a highly ordered structure which leads to their effective interactions with the carbonyl oxygen atoms of 1,2-diketone, thereby increasing the polarization of carbonyl moiety and promoting the cyclo-condensation reaction (Scheme 45).¹⁴³ Lande and co-workers prepared carbon-doped MoO₃-TiO₂ (CMT) material by sol-gel method. For the carbon source, the natural wood

plant *Acacia Arabica* was used. Further, this material was characterized by XRD, SEM, EDS, and FT-IR. The material is with agglomeration and randomness in the particle size with 10–15 nm. Later, this material was applied for the preparation of quinoxaline derivatives from benzil and *ortho*-1,2-diamine in EtOH:H₂O (3:1) solvent system at 40 °C by using the ultrasonication method. The catalyst can be recovered and reused at least three times without significant loss in catalytic activity. The merits of this method are mild reaction conditions, short reaction time, high yield, simple experimental procedure,

Scheme 46 Application carbon-doped MoO₃-TiO₂ (CMT) for the synthesis of quinoxalines.

Scheme 47 Synthesis of quinoxalines using manganese oxide (MnO) nanocrystals.

Scheme 48 MnFe_2O_4 catalyzed synthesis of quinoxalines.

efficient, environmentally benign, and green synthetic protocol (Scheme 46).¹⁴⁴

2.10. Manganese-based nanocatalysts for the synthesis of quinoxalines

Manganese-based nanomaterial has attracted scientists due to its wide range of applications like MRI contrast agents, catalysts, electrode materials, and biomedical materials owing to their unique chemical, physical, and magnetic properties.^{145,146} These materials are used as a heterogeneous catalyst for the synthesis of heterocycles like quinoxalines and the same is discussed in this section. Using an Mn-oleate complex, Kim *et al.*, prepared manganese oxide (MnO) nanocrystals that are single crystalline and uniformly multimodal, with an average distance of 47 nm between the tips. Further, these nanocrystals were utilized as a catalyst for the synthesis of a quinoxaline from an α -hydroxy ketone. The author did the optimization of solvent (DMF, methanol, DCM), temperature, catalyst concentration, and reaction time. The reaction was performed in the presence of DMF at 1.5 mol% *m*-MnO NCs at a temperature of 130 °C for 6 h. Through this method, the reaction rate was remarkably enhanced, and very high conversion was observed. Also, *m*-MnO NCs and *s*-MnO NCs exhibit different activities depending on their shape. The author demonstrated, this by comparing the activities of the *m*-MnO NCs and the *s*-MnO NCs. The spherical MnO nanoparticles were used as catalysts in the synthesis of a quinoxaline derivative. The reaction performed with the use of the *s*-MnO NCs as a catalyst resulted in a low conversion of 60% under the same conditions that provided a higher conversion with the *m*-MnO NCs. The catalyst can regenerate and be reused three times with a slight loss in catalytic activity (Scheme 47).¹⁴⁷

Brahmachari and co-workers used magnetically separable MnFe_2O_4 material as a heterogeneous catalyst for the synthesis of quinoxalines and 2-substituted benzimidazoles at rt under aerobic conditions. The average size of the nanocrystals was in the range of 50–100 nm. Manganese ferrite (MnFe_2O_4) is one of the most important spinel ferrite magnetic oxides where oxygen has fcc close packing and Mn^{2+} and Fe^{3+} ions can occupy either tetrahedral or octahedral interstitial sites. The major advantages of this protocol are easy separation of the heterogeneous catalyst from the reaction mixture, its reusability, high selectivity, room temperature condition, energy efficiency, operational simplicity, clean reaction profiles, and good yields (Scheme 48).¹⁴⁸

2.11. Ruthenium- and zinc-based nanocatalysts for the synthesis of quinoxalines

Sindhuja and co-workers reported Ru complex supported on graphene oxide as a catalyst. The catalyst was used for the synthesis of quinoxaline derivatives from various 2-nitroaniline and hydroxy ketone derivatives *via* the transfer hydrogenation approach. The Ru(II) complexes are homogeneous catalysts that have been heterogenized by supporting it on graphene oxide. The nitroaniline substrates were smoothly combined with the dicarbonyl compound in the presence of a catalyst, and the products were obtained in 65–81% yields. They catalyzed the conversion of 2-nitroaniline and benzoin into 2,3-diphenyl quinoxaline in 8 h with a yield of 83%. The 6-methoxy-substituted quinoxaline and 6,7-dimethyl-substituted quinoxaline were obtained in 66 and 68% yields. In the nitroaniline, with a methyl group, the reaction did not complete even after 24 h, and the maximum conversion was 54% with 100%

Scheme 49 Synthesis of quinoxalines using Ru complex supported on graphene oxide.

Scheme 50 Application of Ru NPs for the synthesis of quinoxalines.

selectivity. The author predicted the plausible pathway for quinoxaline formation, in the first step, there was no formation of diamine from 2-nitroaniline, which confirmed that the first step was imine formation, followed by transfer hydrogenation and cyclization (Scheme 49).¹⁴⁹ Guo *et al.* have prepared Ru NPs on N-doped carbon support and utilized the material for the synthesis of benzimidazoles and quinoxaline acceptor less dehydrogenation coupling (ADC) reaction of diamines with primary alcohols or diols. The Ru/N-C catalyst can be recycled and used up to five times without significant loss of activity. Alkylethane-1,2-diols like propane-1,2-diol, butane-1,2-diol, pentane-1,2-diol, hexane-1,2-diol, octane-1,2-diol, and dodecane-1,2-diol and butane-2,3-diol required higher a diol/molar ratio and a higher temperature (130 °C) to complete the reactions (Scheme 50).¹⁵⁰

Zinc oxide (ZnO) is well known to be highly active, recyclable, non-toxic, and abundantly available for several organic transformations. In this context, Hamid *et al.*, have used ZnO nanoparticle-loaded highly ordered mesoporous silica KIT-6 materials as solid catalysts as an efficient catalyst for the synthesis of various substituted quinoxalines using OPDs and diverse ketones as the reactants at rt in methanol as the solvent. These ZnO nanoparticles with an average particle size of around 9 nm were indeed formed inside the KIT-6-T mesopores with the wet impregnation method. The reaction works out very well with EDG and ERG in OPD (–chloro, –nitro, –dichloro, –cyclohexyl, and bis-OPD) and also various aromatic diketones such as benzyl and furyl which were used to produce various kinds of quinoxaline. The author proposed the plausible mechanism, the catalyst acts as Lewis acid and activates the di-ketone, followed by condensation, to yield the final product (Scheme 51).¹⁵¹

Scheme 51 ZnO-loaded mesoporous silica (KIT-6) as an efficient solid catalyst for synthesis of quinoxalines and its plausible mechanism.

2.12. Palladium- and phosphotungstic acid-based nanocatalysts for the synthesis of quinoxalines

Palladium (Pd) and Pd-based nanomaterial has become an area of intense interest. Pd is well-known for its high affinity for hydrogen, which facilitates the broad use of Pd nanomaterials as primary catalysts, encompassing a wide variety of applications, particularly in organic coupling synthesis, hydrogen detection, purification, and storage.¹⁵² Bardajee and co-workers prepared an SBA-15-supported palladium catalyst containing N–O chelating Schiff-base ligand from SBA-15 and a Pd(II) Schiff-base complex. Further, these materials were characterized by IR, XRD, nitrogen adsorption–desorption method, TEM, and BET analyses. From XRD analysis, the strong peak corresponding to (100) plane and two weak peaks corresponding to (110) and (200) planes of ordered hexagonal mesoporous materials, and TEM analysis reveals Pd(II)-Schiff base/SBA-15 are the ordered channel structure of mesoporous materials which is retained during the complex grafting. The BET analysis showed material exhibited slightly smaller pore volumes, interplanar spacing, and a slightly larger wall thickness. The catalyst/material was applied for the synthesis of quinoxaline,

[1,2-*b*]pyrazine, pyrido[2,3-*b*]pyrazine, and pyrido[3,4-*b*]pyrazine derivatives from 1,2-diamines and 1,2-diketones. In general, Pd/SBA-15 catalyzed reactions produced good to excellent conversions without generating undesirable side products. The OPD-bearing EWG and diamino pyridines were more slowly condensed and needed longer reaction times and electron-rich aromatic diamines gave preferred products in shorter reaction times. Also, Pd/SBA-15 showed excellent reusability over eight successive runs under similar conditions (Scheme 52).¹⁵³ Dâoun *et al.*, prepared nanostructured pyrophosphate Na₂-PdP₂O₇ bifunctional heterogeneous catalyst. The material with average crystallite size was around 7.9 nm with agglomerates in shape. The material was used for the synthesis of quinoxaline derivatives to give a good yield. The variety of substrates used and the presence of EDG such as methyl group on benzene-1,2-diamine substrate did not affect the reaction time and yield. On the other hand, EWG in benzene-1,2-diamine decreased the rate of reaction and yields when compared to unsubstituted substrate. The catalyst can be easily separated and reused in several cycles with a slight drop in the catalytic activity. The main features of the protocols are easy work-up, good yield, short reaction time, and eco-friendly process (Scheme 53).¹⁵⁴

Scheme 52 Synthesis of quinoxaline derivatives catalyzed by Pd/SBA-15.

Scheme 53 $\text{Na}_2\text{PdP}_2\text{O}_7$ as an efficient catalyst for synthesis of quinoxalines and its plausible mechanism.

Phosphotungstic acid (PTA) or 12-tungstophosphoric acid (TPA), as a Keggin-type heteropoly acid, has attracted considerable attention as an acid catalyst in organic transformations because of its high Brønsted acidity, and thermal stability.¹⁵⁵ Masteri-Farahani and co-workers have prepared Keggin-type $\text{Cs(CTA)}_2\text{PW}_{12}\text{O}_{40}$ (CTA = cetyltrimethylammonium cation) nanostructure from aqueous solution of phosphotungstic acid to the microemulsion solution. These materials are star-shaped nanostructures composed of some nanorods with a diameter and lengths of about 100 nm and 500 nm respectively. Further, this material was utilized for the preparation of quinoxaline derivatives from the various 1,2-dicarbonyl and 1,2-diamine under solvent-free conditions. All the reactions proceeded very cleanly giving the desired product without any side product. The catalyst was regenerated by filtration and reused in the fresh

reaction mixture with no significant change in product yield, indicating that the nanostructure was stable during the catalytic cycle. The present methodology has several advantages such as high yields, cleaner reactions, short reaction times, and minimal environmental impact, which make it a useful process for the synthesis of quinoxaline derivatives (Scheme 54).¹⁵⁶ Abdollahi-Alibeik *et al.* have synthesized nano-sized mesoporous silica (MCM-41) supported 12-tungstophosphoric acid (TPA) as a solid acid catalyst and characterized by XRD, FT-IR, and SEM techniques. The material is agglomerated nanoparticles with a size range of less than 100 nm. Further, this catalyst was applied for the synthesis of quinoxalines by the reaction of OPD and 1,2-diketones under solvent-free conditions. The author studied, the effect of the loading amount of TPA on the catalytic activity of TPA/MCM-41 ranging from 5–

41	Ru/N-C, KOH	Toluene	21–88%	150
42	ZnO-KIT-6	MeOH, rt, 10–60 min	83–99%	151
43	Pd(II)-Schiff base/SBA-15	H ₂ O, 100 °C	94–99%	153
44	Na ₂ PdP ₂ O ₇	EtOH, rt	77–98%	154
45	Cs(CTA) ₂ PW ₁₂ O ₄₀	Solvent-free 10–90 min	62–99%	156
46	10 wt% TPA/MCM-41	EtOH, rt	65–99%	157

15 wt% TPA, and the best results were shown at 10 wt% TPA/MCM-41. The various quinoxalines were prepared with EDG and EWG on the OPD and 1,2-diketones, obtained in high to excellent yields. The catalyst TPA/MCM-41 was recovered from the reaction, washed with EtOH, and dried. Further, it can be used for three more cycles without appreciable change in its activity and shows only a slight decrease in the yield after the first run (Scheme 55).¹⁵⁷

3 Conclusion

The quinoxaline ring is an important pharmacophore in modern drug discovery. Therefore, a wide variety of bioactive quinoxalines has been realized as anticancer, antibacterial, anti-inflammatory, antimicrobial, and antiviral agents. Hence, syntheses of this core have become a hot topic for researchers worldwide. Researchers are developing several greener conditions for the synthesis quinoxalines over the last 2–3 decades, especially using the nanocatalyst. This review comprehensively summarizes the role of nanocatalysts for synthesizing

pharmacologically important quinoxaline using *o*-phenylenediamine condensed with various diketone. The catalytic protocols utilizing nanocatalysts and their plausible reaction mechanisms have been discussed throughout the review (Table 1). These nanocatalysts/nanomaterials acts as heterogeneous catalysts were found to be heterogeneous, reusable, economically viable and having an environment-friendly nature. The main advantages of these catalysts were found to render quinoxaline in good yields with easy workup, short reaction time, mild conditions, minimal waste, low cost, atom efficiency, safety, solvent-free (some methods), and possessing excellent functional group tolerance. All the methods followed the same mechanistic pathways revealed condensation, cyclization followed by the use of oxidant or removal of water. However, developing novel methodologies using more efficient catalytic systems to synthesize a variety of biologically active quinoxaline scaffolds with better stereoselectivity, regioselectivity, and chemo selectivity is always in need. The results described in this review will encourage synthetic chemists to develop more

convenient and eco-friendly novel catalytic systems with a high atom economy in the future.

Abbreviations

AMPA	α -Amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid antagonist
receptor	
APTES	(3-Aminopropyl)triethoxysilane
BET	Brunauer–Emmett–Teller
CNQX	6-Cyano-7-nitroquinoxaline-2,3-dione
CNT	Carbon nanotube
CQS	Chloroquinoxaline sulfonamide
DCM	Dichloromethane
DMF	Dimethylformamide
DNA	Deoxyribonucleic acid
DRS	Differential reflectance spectroscopy
EDG	Electron-donating groups
EDX	Energy dispersive X-ray
EWG	Electron withdrawing groups
FTIR	Fourier transform infrared spectroscopy
GO	Graphene oxide
ICP	Inductively coupled plasma
MOF	Metal–organic frameworks
NBQX	2,3-Dioxo-6-nitro-7-sulfamoyl-benzo[f]quinoxaline
nm	Nano meter
NP	Nano particle
OPD	<i>o</i> -Phenylenediamine
PBA	Bisphosphonic acid
POCl ₃	Phosphorus oxychloride
pXRD	Powder X-ray diffraction
rt	Room temperature
SBA-15	Santa Barbara Amorphous-15
SEM	Scanning electron microscopy
SiCN	Siliconcarbonitrite
SMNP	Starch coated maghemite nanoparticles
TEM	Transition electron microscopy
TGA	Thermogravimetric analysis
VSM	Vibrating sample magnetometer
XPS	X-ray photoelectron spectroscopy

Ethical statement

No animals were used.

Data availability

Data are contained in the manuscript. More data can be obtained from the corresponding author through request email.

Author contribution

Dr Rangappa S. Keri: work design and written. Dr Dinesh Reddy: data collection and drawing structures. Dr Srinivasa: formal-analysis; validation; visualization. Dr Vinayak: correction and drawing.

Conflicts of interest

The authors declared that they have no conflict of interest.
