## Acid-induced nitrite reduction of nonheme iron(II)nitrite: mimicking biological Fe–NiR reactions†

Kulbir[,](http://orcid.org/0000-0002-4930-9071)  $\mathbf{D}^a$  Sandip Das,  $\mathbf{D}^a$  Tarali Devi, Somnath Ghosh,  $\mathbf{D}^a$  Subash Chandra Sah[o](http://orcid.org/0000-0003-2557-1937)o **b** and Pankaj Kuma[r](http://orcid.org/0000-0003-2530-7386) **b** \*a

Nitrite reductase (NiR) catalyzes nitrite (NO<sub>2</sub> $^-$ ) to nitric oxide (NO) transformation in the presence of an acid (H<sup>+</sup> ions/pH) and serves as a critical step in NO biosynthesis. In addition to the NiR enzyme, NO synthases (NOSs) participate in NO production. The chemistry involved in the catalytic reduction of  $NO<sub>2</sub><sup>-</sup>$ , in the presence of H<sup>+</sup>, generates NO with a H<sub>2</sub>O molecule utilizing two H<sup>+</sup> + one electron from cytochromes and is believed to be affected by the pH. Here, to understand the effect of H<sup>+</sup> ions on  $NO_2^-$  reduction, we report the acid-induced  $NO_2^-$  reduction chemistry of a nonheme Fe<sup>II</sup>-nitrito complex, [(12TMC)  $Fe^{II}(NO_2^-)]^+$  (Fe<sup>II</sup>–NO<sub>2</sub><sup>-</sup>, 2), with variable amounts of H<sup>+</sup>. Fe<sup>II</sup>–NO<sub>2</sub><sup>-</sup> upon reaction with one-equiv. of acid (H<sup>+</sup>) generates [(12TMC)Fe(NO)]<sup>2+</sup>, {FeNO}<sup>7</sup> (3) with H<sub>2</sub>O<sub>2</sub> rather than H<sub>2</sub>O. However, the amount of H<sub>2</sub>O<sub>2</sub> decreases with increasing equivalents of H<sup>+</sup> and entirely disappears when H<sup>+</sup> reaches  $\cong$  twoequiv. and shows H<sub>2</sub>O formation. Furthermore, we have spectroscopically characterized and followed the formation of H<sub>2</sub>O<sub>2</sub> (H<sup>+</sup> = one-equiv.) and H<sub>2</sub>O (H<sup>+</sup>  $\cong$  two-equiv.) and explained why bio-driven NiR reactions end with NO and H<sub>2</sub>O. Mechanistic investigations, using <sup>15</sup>N-labeled-<sup>15</sup>NO<sub>2</sub><sup>-</sup> and <sup>2</sup>H-labeled-CF<sub>3</sub>SO<sub>3</sub>D (D<sup>+</sup> source), revealed that the N atom in the  ${Fe^{14/15}NO}^7$  is derived from the NO<sub>2</sub><sup>-</sup> ligand and the H atom in H<sub>2</sub>O or H<sub>2</sub>O<sub>2</sub> is derived from the H<sup>+</sup> source, respectively. **EDGE ARTICLE**<br> **(a)** Cheek for undates<br> **Acid-induced nitrite: reduction of nonherne irons (a)<br>

<b>Acid-induced nitrite: community biological Fe—NiR reactions** the state form of the state form of the sta

Nitric oxide (NO), a critical biological component, participates in numerous bio-physiological processes such as neurotransmission, vascular regulation, inhibiting platelet aggregation, and immune response to multiple infections at nanomolar concentration.<sup>1</sup> Also, NO is known to be involved in plant growth and development.<sup>2</sup> NO meagerness may cause pathogenic effects such as atherosclerosis, diabetic hypertension, etc.<sup>3</sup> However, at micromolar concentrations, NO is highly toxic and utilized for immune defense against harmful pathogens,<sup>4</sup> in addition to its oxidized species, i.e., peroxynitrite (ONOO<sup>−)5</sup> or/nitrogen dioxide (' $NO<sub>2</sub>$ ).<sup>6</sup> In contrast to the immune response towards pathogens, oxidized NO species also show various toxicological actions in biological systems.<sup>5b,7</sup>

Hence, sensible production of NO is required to maintain physiological homeostasis and is usually achieved by two metalloenzymes, *i.e.*, NO synthases (NOSs)<sup>8</sup> and/or nitrite reductases (NiRs).<sup>8</sup>a,9 NOS enzymes are heme-proteins that generate NO by catalyzing the conversion of L-arginine to L-citrulline under aerobic

conditions.<sup>8b,c</sup> However, under ischemia and hypoxic conditions, the suppression of NOS activity results in the decrease of NO generation. Under such conditions,  $NO_2$ <sup> $-$ </sup> works as an active NO source in biological systems, generating NO in acid-induced  $\mathrm{NO_2}^$ reduction reactions.<sup>10</sup> Sometimes, under abnormal conditions, biochemical dysfunction may cause NO overproduction by NiRs or NOSs. Under such conditions, NO dioxygenase (NOD) enzymes available in vivo convert excess NO to biologically benign nitrate  $(NO<sub>3</sub><sup>-</sup>)<sup>11</sup> NO<sub>3</sub><sup>-</sup>$ , the product of the NOD reaction, serves as a critical component of  $NO<sub>2</sub><sup>-</sup>$  generation and a precursor to the biological NO cycle.<sup>12</sup> In humans, commensal bacteria in the oral cavity play a vital role in converting  $NO<sub>3</sub><sup>-</sup>$  to  $NO<sub>2</sub><sup>-</sup>.<sup>12a</sup>$  Bacteria reduce  $NO_3$ <sup>-</sup> to  $NO_2$ <sup>-</sup> via an OAT reaction mediated by molybdenum-based NR enzymes.<sup>13</sup> The interconversion of  $NO<sub>3</sub>$ to/NO<sub>2</sub><sup> $-$ </sup>/to NO (or *vice versa*) is the critical step of the denitrification process.<sup>14</sup> In vivo studies have proven that  $NO_2^-$  is a fundamental source of NO in mammalian or bacterial systems, an intermediate species of the biological nitrogen cycle (NO<sub>3</sub><sup>-</sup>  $\rightarrow$  $NO_2^- \rightarrow NO \rightarrow N_2O \rightarrow N_2$ ).<sup>14</sup> At the bio-physiological level,  $NO_2^$ gets reduced to NO, primarily by globins<sup>15</sup> or by acid-catalyzed  $NO_2$ <sup>-</sup> reduction in the stomach<sup>16,17</sup> or by Fe/Cu-NiR enzymes/ cytochrome c oxidase (CcO)/xanthine oxidase,<sup>18</sup> which reduces  $NO_2^-$  to NO in the presence of two-equiv. of H<sup>+</sup> ions, *i.e.*,<sup>8a,9,15</sup>

However, few functional mimicking models were developed and investigated in vivo/in vitro to explore the mechanistic insight of microbial NiR enzymatic chemistry. Brooks and coworkers proposed the NiR activity of mammalian hemoglobin (Hb) protein under anaerobic conditions, which converts  $\mathrm{NO_2}^$ to NO with the formation of metHb.<sup>19</sup> E. T. Papish et al. explored the Cu-NiR chemistry and showed NO production with  $H_2O$  as a side product via a Cu<sup>I</sup>–NO<sup>+</sup>  $\leftrightarrow$  Cu<sup>II</sup>–NO intermediate in the reaction of Cu–NO<sub>2</sub><sup>-</sup> with two-equiv. of H<sup>+</sup>.<sup>20</sup> A heme-Fe/Cu assembly model has been developed to mimic the cytochrome c oxidase, illustrating the reversible conversion of  $\mathrm{NO_2}^-$  to  $\mathrm{NO.^{21}}$ For the first time, Murphy and coworkers explored the explained Cu–NO $_2^-$  reduction reaction to release NO via the {CuNO} intermediate and characterized it structurally.<sup>9</sup>b,22 Patra and coworkers have mimicked NO $_2^-$  reduction reactivity using Cu<sup>II</sup>–NO<sub>2</sub>  $^-$  with two-equiv. of H $^+$  and one e $^-$ , leading to NO and H2O molecule formation.<sup>23</sup> Lehnert and coworkers have explored electrocatalytic reduction using Cu<sup>II</sup>–NO<sub>2</sub>  $^-$  producing NO in aqueous media<sup>24</sup> and compiled the electronic structure and reactivity of the biologically relevant coordination chemistry of iron and NO.<sup>15</sup> In addition to acid-encouraged  $NO<sub>2</sub><sup>-</sup>$  reduction to NO in different model systems. Various models have been explored for the reduction of metal-bound  $NO_2$  to NO *via* (i) oxygen atom transfer (OAT) caused by  $(\mathrm{R}_2\mathrm{S})^{25}/\mathrm{thiol}$   $(\mathrm{RSH})\}^{18a,26}/\mathrm{triphenylphosphine}$   $(\mathrm{PPh}_3)^{27}/\mathrm{vanadium}$ chloride  $(VCl<sub>3</sub>)<sup>28</sup>$  and (ii) photo-induced reactions<sup>29</sup> of metalbound nitrite  $(M-NO_2^-)$ . Chemical Science Wave on 23 February 2023. Downloaded on 23 February 2023. In addition to the developments on biomimetic synthetic modeling of M–NOs/or active sites associated with NiR and/or NOS.<sup>11</sup>d,30 Recently, Lehnert and coworkers have established the synthetic strategy for Fe–NOs, $31$  and Nam and coworkers have explored the photo-induced NiR reactivity of  $Fe-NO_2$  to generate Fe–NOs and also stabilize Co–NOs.<sup>32</sup> Ford and coworkers continuously discover the NiR chemistry of various heme systems.<sup>33</sup> Although NiR is the key source of NO in the biological system, such reactions are not investigated extensively to characterize the intermediates and transition states of  $\mathrm{NO_2}^-$  reduction reactions. Hence, several research groups are working to understand the proper  $\mathrm{NO_2}^-$  reduction reaction mechanism. There are only very few reports on acid-induced  $NO<sub>2</sub><sup>-</sup>$  reduction reactions to mimic NiR enzymatic reactions and understand the mechanistic aspects.<sup>9b,29,34</sup> In this investigation, we intend to characterize different intermediates of  $\operatorname{H}^{\text{+}}$ induced  $\mathrm{NO_2}^-$  reduction in  $\mathrm{Fe}^\mathrm{II}\text{--NO_2}^-$  and its reaction products and then explore its mechanistic aspects. This report will focus on how different amounts of acid  $(H<sup>+</sup> ion)$  affect the reaction mechanism and regulate the side products in addition to NO.

Herein, we report the  $NO_2^-$  reduction chemistry of a nonheme FeII–NO<sub>2</sub><sup>−</sup> complex, [ $(12TMC)Fe<sup>H</sup>(NO<sub>2</sub><sup>−</sup>)]<sup>+</sup>$  (2), bearing the 1,4,7,10-tetramethyl-1,4,7,10-tetraazacyclododecane (12TMC) ligand (Scheme 1, reaction I). Complex 2 reacts with one-equiv. of triflic acid (HSO3CF3,  $H^+$  source) and generates the corresponding nonheme Fe–nitrosyl complex, [(12TMC) Fe(NO)]<sup>2+</sup>({FeNO}, 3), and H<sub>2</sub>O<sub>2</sub> (Scheme 1, reactions II & III) in CH3CN at 233 K. However, upon reaction with a base (OH−), 2 does not form 3. Mechanistic investigations using <sup>15</sup>N-labeled-<sup>15</sup>  $\mathrm{NO_2}^-$  demonstrated explicitly that the N atom in the NO moiety

of 3 is derived from the  $NO_2^-$  anion and  $H_2O_2$  by the protonation of the O atom of the  $NO_2^-$  moiety. Conversely, an increased H<sup>+</sup> concentration showed a significant fall in  $H_2O_2$ , which disappeared completely when the H<sup>+</sup> ion quantity was  $\cong$ two-equiv. with the simultaneous formation of a substantial amount of  $H<sub>2</sub>O$  (Scheme 1, reaction IV). To the extent of our knowledge, the present work reports the very first comparative study for the reaction of an  $\mathrm{Fe}^{\mathrm{II}}\text{-}\mathrm{NO_2}^-$  complex with varying  $\mathrm{H}^+$ concentrations and the evidence showing the formation of  $H_2O_2$  (one-equiv. of H<sup>+</sup>) and  $H_2O$  ( $\cong$  two-equiv. of H<sup>+</sup>), illustrating a new approach for NiR enzyme activity (Scheme 1).

#### Results and discussion

#### Preparation of the Fe $^{\mathrm{II}}$ -nitrito complex, [(12-TMC)Fe $^{\mathrm{II}}(\mathrm{NO_2}^-)]^+$ (2)

The initial FeII–NO $_2^-$  complex, [(12TMC)Fe $^{\rm II}$ (NO $_2^-$ )] $^+$  (2), was prepared by the addition of one equivalent of  $NaNO<sub>2</sub>$  in the presence of a 15-crown-5 to  $Fe<sup>H</sup>$ -complex, [(12TMC)  $[Fe^{II}(NACH<sub>3</sub>)]^{2+}$  (1), in CH3CN at 298 K (Scheme 1 & reaction I; also see the ESI and Experimental section (ES)). Complex 2 was further characterized by various spectroscopic measurements, including the determination of the single-crystal X-ray structure. A UV-vis absorption band ( $\lambda_{\text{max}} = 325$  nm and  $\epsilon = 356 \text{ M}^{-1}$  $\rm cm^{-1})$  was formed upon adding an equivalent amount of NaNO $_2$ to the CH<sub>3</sub>CN solution of 1, which corresponds to 2 (Fig. 1a). A characteristic peak for metal-bound  $NO<sub>2</sub><sup>-</sup>$  stretching at 1270  $cm^{-1}$  was observed in the FT-IR spectrum of 2, which shifted to 1247  $cm^{-1}$  when 2 was prepared using <sup>15</sup>N-labeled-nitrite  $(^{15}{\rm N}^{16}{\rm O}_2^-)$  (inset: Fig. 1a andS1; ESI†).<sup>35</sup> The electrospray ionization mass spectrum (ESI-MS) recorded for 2 showed a prominent ion peak at  $m/z$  330.1, which shifted to m/z 331.1 when prepared with <sup>15</sup>N-labeled Na<sup>15</sup>N<sup>16</sup>O<sub>2</sub>, and their mass and isotope distribution pattern corresponds to [(12TMC) Fe(NO<sub>2</sub>  $^-)]^+$  (calc. *m/z* 330.1) and [(12TMC)Fe( $^{15}$ NO<sub>2</sub>  $^-)$ ] $^+$  (calc. *m/z* 331.1), respectively (Fig. 1b and S2; ESI<sup>†</sup>). The <sup>1</sup>H-NMR spectrum of 2 showed fairly clean paramagnetic proton signals for the protons of the 12TMC ligand (Fig. S3a†), suggesting a magnetically active Fe center. The spin-state of the Fe center in 2 was determined by calculating the magnetic moment of the  $Fe<sup>H</sup>$  center by Evans' method and found to be 5.19 BM, suggesting a high spin Fe<sup>II</sup> ion (S = 2) in complex 2 (ESI,<sup>†</sup> ES, Fig. S3b). The electrochemical measurement of 2 showed

Fig. 1 (a) UV-visible spectra of 1 (0.50 mM, black line) and 2 (0.50 mM, red line) in CH<sub>3</sub>CN under Ar at 298 K. Inset: IR spectra of  $2^{-14}$ NO<sub>2</sub><sup>-</sup> (red line) and  $2^{-15}$ NO $_2^-$  (blue line) in KBr. (b) ESI-MS spectra of 2. The peak at 330.1 is assigned to  $[(12TMC)Fe^{II}(NO<sub>2</sub>^-)]^+$  (calcd  $m/z$  330.1). Inset: isotopic distribution pattern for  $2^{-14}$ NO<sub>2</sub><sup>-</sup> (red line) and  $2^{-15}$ NO<sub>2</sub><sup>-</sup> (blue line).

a reversible cyclic voltammogram (redox potential  $+$  0.56 V vs. Ag/AgNO $_3^{-}$ ) (ESI, Fig. S4a†). In addition to the above spectral measurements, the structural details of 2 were obtained by its single-crystal X-ray structure determination (Fig. 2). The  $Fe<sup>H</sup>$ center of 2 was found to have O, O $^\prime$ -chelated bi-dentate NO2 $^$ anions in a distorted octahedral geometry (ESI,† ES, Fig. S5 and Tables 1 & 2).

#### The nitrite reduction reaction of the Fe $\mathrm{^{II}}$ –NO $_2^{-}$  complex (2)

To further investigate the  $NO_2^-$  reduction chemistry of FeII–  $\mathrm{NO_2}^-$  (2), we explored its reaction with different equivalents of acid  $(H^+$  ions). When 2 was reacted with  $H^+$ , we observed a visible color change from yellow to green and a new absorption band ( $\lambda_{\text{max}} = 350$  nm and  $\epsilon = 1450 \text{ M}^{-1} \text{ cm}^{-1}$ ), characteristic of a new species (3), formed over ∼2 minutes in CH3CN under Ar at 233 K (Fig. 3a; ESI, $\dagger$  ES, and Fig. S6).<sup>8a,9</sup> Complex 2 was found to be very stable in CH<sub>3</sub>CN and at 298 K as it did not

Fig. 3 (a) UV-visible spectral changes of 2 (0.50 mM, black line) upon addition of  $H^+$  (one-equiv.) in CH<sub>3</sub>CN at 233 K. Black line (2) changed to a red line (3) upon addition of  $H^+$ . Inset: IR spectra  $3-14$ NO (red line) and 3-<sup>15</sup>NO (blue line) in KBr. (b) ESI-MS spectra of 3. The peak at 463.1 is assigned to  $[(12TMC)FeII(NO)(OTf)]+$  (calcd  $m/z$  463.1). Inset: isotopic distribution pattern for 3-14NO (red line) and 3-15NO (blue line). (c) Time-dependent EPR spectra of the generation of 3 (red line) in the reaction of 2 and  $H^+$  (one-equiv.) in CH<sub>3</sub>CN at 77 K.

show any spectral variations in the absence of  $H^+$  (ESI, $\dagger$  Fig. S7a). Complex 2 was also found inert towards OH− as it does not indicate any change in UV-vis spectra when treated with tetrabutylammonium hydroxide (ESI, Fig. S7b†), suggesting that Fe–  $\mathrm{NO_2}^-$  reacts only with  $\mathrm{H}^+.$  The amount of  $\mathrm{H}^+$  required to reduce the  $NO_2^-$  moiety was determined by spectral titration, which confirmed the ratio-metric equivalent of 2 with  $H^+$  as 1:1 (ESI,<sup>†</sup> Fig. S8). The compound 3, obtained in the reaction of 2 with H+ was determined to be an Fe-nitrosyl complex,  ${[FeNO]}^7$ , based on various spectroscopic characterization techniques (vide *infra*). The other product of the  $NO<sub>2</sub><sup>-</sup>$  reduction using oneequiv. of  $H^+$  was determined to be  $H_2O_2$ , in contrast to previous reports on biological NiR and  $NO_2^-$  reduction chemistry, via a proposed thermally unstable ONOH intermediate as reported in the literature (Scheme 1, reactions II & III).<sup>36</sup> However, when reacted with more than one-equiv. of  $H^+$  ( $\cong$  two) 2 generated 3, but the amount of  $H_2O_2$  decreased gradually with

increasing H $^+$ . This suggests the decomposition of  $\rm{H_2O_2}$  or utterly new chemistry in the presence of more than one-equiv. of  $H^+$ ; the new product was confirmed to be  $H_2O$  by using various spectral measurements (Scheme 1, reaction IV). To the best of our knowledge, this work reports the first-ever study where the side products of  $\mathrm{NO_2}^-$  reduction are regulated by different amounts of  $H^+$ , which opens a new pathway of acidinduced  $\mathrm{NO_2}^-$  reduction chemistry to the scientific community.

We have performed various spectral measurements to track the products of H $^+$  (or D $^+$ )-induced reduction of Fe-bound  $^{14/}$  $^{15}NO_2^-$  in 2. The FT-IR spectrum of 3 showed a characteristic peak for Fe-bound nitrosyl stretching at 1783 cm $^{-1}$  ({Fe $^{14}$ NO}<sup>7</sup>), which shifted to 1755 cm $^{-1}\left(\{{\rm Fe}^{15}{\rm NO}\}^{7}\right)$  when 3 was prepared by the reaction of <sup>15</sup>N-labeled-nitrite  $(2^{-15}NO_2^-)$  with one-equiv. of  $H^+$  (inset, Fig. 3a and S9; ESI†). This shifting in NO stretching frequency ( $\varDelta =$  28 cm $^{-1})$  indicates that the N atom in NO moiety is derived from the  $\mathrm{^{14/15}NO_{2}}^{-}$  ligand of 2. Similarly, the ESI-MS spectrum of 3 showed a prominent peak at  $m/z$  463.1, [(12TMC) Fe(NO)(OTf)]<sup>+</sup> (calc.  $m/z$  463.1), which shifted to 464.1, [(12TMC) Fe( $^{15}$ NO)(OTf)] $^{\scriptscriptstyle +}$  (calc. *m*/z 464.1), when Fe $^{\mathrm{II}-15}$ NO<sub>2</sub>  $^-$  was reacted with  $H^+$  (Fig. 3b and S10; ESI†), specifying clearly that NO in 3 is derived from the  $NO_2^-$  moiety. The <sup>1</sup>H-NMR spectrum of 3 showed shifting in the <sup>1</sup>H-signals of the 12TMC ligand framework suggesting a paramagnetic system (ESI, Fig. S11a†).<sup>32a,b</sup> We determined the spin-state of the Fe centre in 3 by calculating its magnetic moment using Evans' method and found it to be 2.3 BM, suggesting a low-spin Fe center in 3 ( $S = 1/2$ ) for the complex 3 (ESI, ES, and Fig.  $S11b\dagger$ ).<sup>37</sup> Additionally, timedependent EPR measurements were followed for the generation of 3 in the reaction mixture of  $2 + H^+$ . EPR measurements (77 K), performed at different time intervals, showed the formation of a new species  $(g = 2.04)$  (Fig. 3c), which is characteristic of the EPR signal of isolated species  ${FeNO}^7$  (Scheme 1, reaction V), confirming the formation of low-spin 3 in the above reaction (ESI, Fig. S11c†). The electrochemical measurement of 3 showed a reversible cyclic voltammogram (redox potential + 0.36 V vs. Ag/AgNO<sub>3</sub><sup>-</sup>) (ESI, Fig. S4b†). Additionally, we have determined the binding constants  ${\it K}_{\rm b}({\rm Fe}^{\rm II}{\rm -NO_2}^-)$  and  $K_{\rm b}$ {[Fe(NO)}<sup>7</sup> using the Benesi-Hildebrand equation<sup>28,38</sup> for the generation of 2 and 3 in the reaction of  $[(12TMC)Fe<sup>H</sup>(CH<sub>3</sub>CN)]<sup>2+</sup>$ with NO<sub>2</sub><sup>−</sup> and NO. The values were  $K_\text{b}\text{(Fe}^{\text{II}}\text{-N}\text{O}_2^{\text{}}\text{)} = 4.7 \times 10^{2}$  $M^{-1}$  &  $K_b$ {[FeNO} = 8.4 × 10<sup>2</sup> M<sup>-1</sup> (ESI,† ES, and Fig. S12), which also supports the forward reaction. In addition, the yield for the formation of 3 was calculated by comparing the UV-vis absorption spectra of 3 formed in the reaction of 2 with oneequiv. of H<sup>+</sup> with the authentic Fe–nitrosyl complex ({FeNO}<sup>7</sup>), prepared in a separate reaction of  $[(12TMC)Fe<sup>H</sup>(CH<sub>3</sub>CN)]<sup>2+</sup>$  + NO, and was found to be 95%. However, the yield decreased to 85% when the reaction was carried out using two-equiv of  $H^+$ (ESI, ES, and Fig. S13†). Furthermore, the structural details of 3, obtained in the reaction of 2 and  $H^+$ , were obtained by its singlecrystal X-ray structure determination (ESI, ES & Fig. 4). The NO moiety showed the coordination via the N atom to the Fe center of 3 with the a angle of 168° (ESI, ES Fig. S14;† & Tables T1 and T2). This arrangement suggests a neutral 'NO moiety with an  $Fe<sup>H</sup>$  center<sup>37,39</sup> (further supported by BVS calculation from the crystal parameters of 3, ESI,† ES) and can be formulated as Chemical Science<br>

#### Mechanistic investigation of  $NO_2^-$  reduction

*In vivo* and *in vitro* biomimetic studies on acid-induced  $NO_2^$ reduction reactions produce NO with  $H<sub>2</sub>O$  (as explained in the biological NiR chemistry)<sup>34a,40</sup> or in some cases 'OH  $(H_2O_2)^{36}$  or a metal hydroxide<sup>41</sup> and should be accomplished via the proposed ONOH intermediate, as reported by Murphy et  $al.^{9b}$  and Rose et al.<sup>40g</sup> for the biological Cu-NiR chemistry. Similarly, Fujii and coworkers also proposed a Cu(ONOH) intermediate in the acid-induced biomimetic  $NO_2^-$  reduction on the Cu<sup>I</sup> center.<sup>40h</sup> Meanwhile, Shigeta et al.<sup>40i</sup> & Chen and coworkers<sup>40j</sup> theoretically established the presence of a Cu(ONOH) intermediate in acid-induced  $NO_2^-$  reduction. The present work elucidated how varying equivalents of  $\text{H}^+$  ions determine the side products of Fe $^\text{II}$ . bound  $NO_2^-$  reduction chemistry in addition to NO and should be accomplished by a similar proposed ONOH intermediate. In this regard, we proposed the reaction sequences, where the preliminary step of the  $NO<sub>2</sub><sup>-</sup>$  reduction reaction consists of an electrophilic addition of  $H^+$  to the  $NO_2^-$  anion of 2 and generating the suggested  $[Fe-ONOH]^{2+}$  intermediate species (Scheme 2, reaction I), as proposed previously.<sup>36,41</sup> The presumed  $[Fe-(ONOH)]^{2+}$ intermediate is believed to produce  ${FenO}^7$  via the homolytic cleavage of the ON–OH moiety, as reported in  $NO_2^-$  reduction on

the Fe<sup>II</sup> center and Cu-NiR,<sup>36,41</sup> and 'OH  $(^{1}/_{2}$  H<sub>2</sub>O<sub>2</sub>)<sup>42</sup> (Scheme 2, reaction II). In contrast,  $NO_2^-$  reduction in the presence of  $\approx$ two-equiv. or more  $H^+$  produced 3 with  $H_2O$  as a side product in a multiple-step reaction (Scheme 2, reaction III). This reaction is believed to occur *via* the reduction of the  $NO_2^-$  anion of 2 in the presence of two  $H^+$ , as reported in biological Ni $R^{9b,40g}$  and biomimetic  $NO_2^-$  reduction<sup>40h–j,43</sup> reactions. The H<sub>2</sub>O molecule may be generated either by (a) step-wise protonation of NO $_2^-$  species of 2  $\,$ as observed in biology, $4^{\omega a,b}$  (b) acidic decomposition of  $\mathrm{H}_2\mathrm{O}_2$ , $^{44}$  or (c) by auto-decomposition of  $H_2O_2$ .<sup>45</sup>

To validate our proposed  $H^+$ -induced  $NO_2^-$  reduction chemistry mechanism, we have reacted 2 with different equivalents of  $H<sup>+</sup>$  and characterized all the products formed in the reaction mixture. In both the acid-induced reactions, we observed the formation of 3. However, the side product of  $\mathrm{NO_2}^$ reduction changed to  $H_2O$  instead of  $H_2O_2$  when the H<sup>+</sup> amount was  $\ge$  two-equiv. (ESI,† ES). H<sub>2</sub>O<sub>2</sub>/& H<sub>2</sub>O formed in the NO<sub>2</sub><sup>-</sup> reduction reaction was followed/characterized and quantified using <sup>1</sup>H-NMR spectroscopic measurements. A characteristic signal for  $H_2O_2$  (8.66 ppm, ESI,† Fig. S15a)<sup>46</sup> was observed in the <sup>1</sup>H-NMR spectrum of 2 with one-equiv. of  $H^+$  in CD<sub>3</sub>CN. Our proposal of  $\rm{H_2O_2}$  formation in one-equiv. of  $\rm{H}^+$  induced  $\rm{NO_2}^$ reduction was authenticated by comparing this spectrum with those of the authentic samples: (i)  $H_2O_2$  plus 3 (8.66 ppm; ESI,<sup>†</sup> Fig. S15b) and (ii)  $H<sub>2</sub>O<sub>2</sub>$  only (8.66 ppm; ESI, $\dagger$  Fig. S15c).<sup>46</sup> The amount of  $H_2O_2$  in the above reaction was confirmed to be more than 50% (defining  $\frac{1}{2}$  equivalent of  $\text{H}_{2}\text{O}_{2}$  relative to 2 as 100% yield) from  $^1\mathrm{H}\text{-}\mathrm{NMR}$  spectral measurements and using benzene as the internal standard (ESI,<sup>†</sup> ES, and Fig. S15a).<sup>46</sup> Time-based <sup>1</sup>H-NMR spectral measurements for the above reaction showed the gradual formation of  $H_2O_2$  (8.66 ppm), which starts decreasing after reaching its maxima, suggesting the decomposition of  $H_2O_2$  to  $H_2O$  (Fig. 5a).<sup>44,45</sup> In addition to <sup>1</sup>H-NMR, iodometric titration likewise confirmed  $H_2O_2$  formation in the reaction of 2 with one-equiv. of  $H^+$  which was determined to be  $\sim$ 65% (ESI, ES, and Fig. S16a†) (defining 1/2 equivalent of H<sub>2</sub>O<sub>2</sub> relative to 2 as 100% yield). However, no  $H_2O_2$  was observed in iodometric titration when the reaction was carried out in the presence of two-equiv. of  $H^+$  (ESI, ES, and Fig. S16b†).<sup>47</sup> Edge Article. Chemic and Original article. The meaning on the present of the present on 23 February 2023. Download article is like the set of the mean of the mea

Fig. 5 1H-NMR spectrum of (a)  $H_2O_2$  formation and (b)  $H_2O$  formation in the reaction of 2 with one-equiv.  $\theta$  two-equiv. of H<sup>+</sup> in CD<sub>3</sub>CN recorded at different times, respectively. The state of the state

Furthermore, we have also established  $H<sub>2</sub>O$  formation in the  $\mathrm{NO_2}^-$  reduction reaction in the presence of two-equiv. of  $\mathrm{H}^+$  by <sup>1</sup>H-NMR spectroscopic measurements (Fig. 5b and S15d, ESI<sup>†</sup>). To establish that  $H^+$  is only responsible for forming  ${}^1H\text{-NMR}$ signals at 2.2 ppm, we have explored the same reaction using  $\rm CF_3SO_3D$  (D<sup>+</sup> source). Surprisingly, when the source was D<sup>+</sup>, we did not observe the formation of the  $H_2O$  peak (at 2.2 ppm); this clearly suggests that  $H^+$  ions are responsible for the  $H_2O$ formation in the two-equiv. of  $\text{H}^+$  induced  $\text{NO}_2\text{ }^-$  reduction (ESI, ES, and Fig. S17†). In addition, time-dependent <sup>1</sup>H-NMR spectral measurements for the reaction of 2 with two-equiv. of  $H^+$ showed an increment in the peak of  $H<sub>2</sub>O$  protons and a kind of first time-base measurement, further supporting our proposal of H2O formation (Fig. 5b). However, our efforts to quantify the amount of  $H<sub>2</sub>O$  formed in the reaction are futile; but they scientifically established the mechanistic aspect of acidinduced  $NO_2$ <sup>-</sup> reduction in the presence of different equivalents of  $H^+$ . These results are the only example where tracking H<sup>+</sup>-induced  $NO_2^-$  reduction products has confirmed that the variable amounts of  $H^+$  (pH/acidic conditions) generate NO with  $H_2O_2$  (one-equiv. of H<sup>+</sup>) or  $H_2O$  (≥two-equiv. of H<sup>+</sup>).

Furthermore, we attempted to characterize the proposed  $[Fe-ONOH]^{2+}$  intermediate to illustrate its conversion mechanism to 3. However, after several attempts, we failed to detect/ stabilize the intermediate even at low temperature (193 K) in UV-vis & FT-IR spectroscopic measurements, suggesting a kinetically driven reaction.<sup>48</sup> Since metal-nitrous acid intermediates are known to be highly unstable intermediates, $34b,36,40h-j$  there are only a few reports about the metal-bound nitrous acid species.<sup>34b,40h,40j,49</sup> However, to support our mechanistic proposal for the formation of an 'OH radical  $(H<sub>2</sub>O<sub>2</sub>)$  via the homolytic cleavage of the N-O bond, we pursued the 'OH radical trapping experiment using 2,4-di-tert-butylphenol (2,4-DTBP).<sup>50</sup> In the one-equiv. of  $H^+$  induced  $NO_2^$ reduction reaction, we have observed the formation of 3,5-Ditert-butylcatechol (3,5-DTBC,  $\sim$ 22%) and 2,4-DTBP-dimer (2,4-DTBP-D,  $\sim$ 8%) with a minimal amount of nitro-2,4-DTBP (NO<sub>2</sub>-2,4-DTBP, ∼6%) (ESI, ES, and Fig. S18 & S19†). The generation of 3,5-DTBC<sup>51</sup> in the above experiments undoubtedly confirmed the 'OH formation via the N–O bond homolysis of the ON–OH moiety. Hence, the formation of 3,5-DTBC and other products confirms the reaction sequences (Scheme 3) and supports the

presence of the  $[Fe-(ONOH)]^{2+}$  intermediate in the one-equiv. of H<sup>+</sup> induced  $NO_2$ <sup>–</sup> reduction reaction.

The transformation of 2,4-DTBP in the presence of oneequiv. of  $H^+$  can be explained based on the radical coupling reaction.<sup>51</sup> The sequences of the 2,4-DTBP conversion are believed to be (i) the generation of the phenoxyl radical and the release of Fe–NOs by the H-atom abstraction reaction of [Fe– ONOH $]^{2+}$  from DTBP (Scheme 3, reaction I & II). After that, the phenoxyl radical either (ii) dimerizes to give 2,4-DTBP-D (Scheme 3, reaction III) or (iii) produces 3,5-DTBC upon radical coupling with another molecule of  $[Fe-ONOH]^{2+}$  and releases 3 (Scheme 3, reaction IV). In some cases,  $NO<sub>2</sub>-DTBP$ and 3 may generate in the presence of two molecules of [Fe– ONOH $]^{2+}$  and a phenoxyl radical (Scheme 3, reaction V). Also, when the above radical trapping experiments were performed using  $CF_3SO_3D$ , we observed the generation 'OD-driven products of DTBC (ESI,† ES, and Fig. S20). In addition, we reacted  $\rm 2^{-16}O^{14}N^{18}O^-$  with one equiv. of  $\rm H^+$  in the presence of 2,4-DTBP. Surprisingly, we observed the formation of 3,5-DTBC  $(^{18}OH)$ with  ${}^{16}O^{14}N{}^{18}O$ -DTBP as a side product (ESI, Fig. S21†). These experiments support that one equiv. of  $H^+$  induced  $NO_2^$ reduction in 2 generates  $3 + H_2O_2$  via the homolytic cleavage of the N-O bond of the ON-OH intermediate.<sup>36</sup> Chemical Science<br>

### Conclusion

The mechanistic investigation of acid-induced  $NO_2^-$  reduction became an important research topic in modern-day chemistry as it deals with  $NO_2$ <sup>-</sup> to NO transformation, an essential signaling molecule in biosystems.<sup>40b,52</sup> The mechanistic aspects of NiR chemistry mediated by  $H^+$  are still challenging to the scientific community and yet to be resolved as two different side products have been proposed to form in vivo and in vitro studies.<sup>8a,9,16,25,30</sup> Also, the pH/or H<sup>+</sup> ion concentration effect is yet to be confirmed as it affects the reaction mechanism and the side products of  $NO_2^-$  reduction reactions.<sup>48</sup> In this report, we have shown the reduction of  $NO_2^-$  in a nonheme  $Fe^{II}$ -nitrito complex,  $[(12 \text{T} \text{MC}) \text{Fe}^{\text{II}}(\text{NO}_2^{-})]^+$  (2), to an Fe–nitrosyl complex  $[(12TMC)Fe(NO)]^{2+}$ ,  ${FeNO}^{7}$  (3), in the presence of different equivalents of H<sup>+</sup> (CF<sub>3</sub>SO<sub>3</sub>D, D<sup>+</sup> ion source), a biomimetic functional model of NiR. The structural details of  ${FenO}^7$ showed an axially coordinated NO moiety to the Fe center. In addition,  $^{15}$ N-labeled  $^{15}$ NO<sub>2</sub>  $^-$  experiments confirm that the N atom of the NO moiety in 3 is derived from the NO $_2^-$  anion of 2. Acid-induced  $NO_2^-$  reduction of 2 showed the formation of  ${FenO}^7$  along with  $H_2O_2$  or  $H_2O$  as a side product when treated with different ratios of  $H^+$ , one-equiv. or  $\geq$ two-equiv., respectively. Reports on acid-induced biomimetic  $NO_2^-$  reduction<sup>40h,j,43</sup> and biological NiR reactions<sup>9b,40g,41</sup> suggested a metal-ONOH intermediate before NO formation; hence, we believe that the H $^+$ -induced NO<sub>2</sub> $^-$  reduction on the Fe $^{\rm II}$  center in 2 should generate 3 via the proposed  $[Fe-ONOH]^{2+}$  intermediate and follow the NiR chemistry. The N–O bond homolysis of the proposed ONOH intermediate was supported by the observation of 3,5-DTBC-<sup>16</sup> OH( $^{18}$  OH) in 'OH radical trapping experiments using 2,4-DTBP $^{\rm 51}$  in the reaction of 2-ON $^{\rm 16} \rm O_2^{- (16} O N^{18} O^-)$ with one equiv. of  $H^+$ . Also, the observation of  $\mathrm{DTBC}(\mathrm{OD})$  in the

presence of  $D^+$  further supports the acid-induced reduction of  $NO_2$ <sup>-</sup>. In addition, a significant amount of  $H_2O_2$  formation was also confirmed using <sup>1</sup>H-NMR/or UV-vis iodometric titration along  $3.^{46}$  However, the generation of the  $H_2O$  molecule was believed to occur either (i) by  $\rm NO_2^-$  reduction in the presence of two-equiv. of  $H^+$  and an electron<sup>9b,40c,40g,40h,40j</sup> or (ii) by the acidinduced decay of  $H_2O_2$  or auto-decomposition of  $H_2O_2$ .<sup>44,45</sup> The redox potential of 2 was higher than that of the enzymatic iron-site, making 2 more prone to reduction.<sup>53</sup> At this time, we are not sure about the source of another electron; however, we are currently exploring various  $NO_2^-$  bound  $Cu^{I/II}$  &  $Fe^{II/III}$ complexes to understand the reaction sequences and track the electron source using the known electron donor species. These results provide entirely new reaction sequences for acidinduced  $NO_2^-$  reduction chemistry, a functional model of biomimetic NiR chemistry, and show how the  $H^+$  ion concentration determines  $H_2O_2$  or  $H_2O$  as a side product along with NO.

## Experimental Section

For the experimental details, see the ESI.†

## Data availability

All the required data is already provided in the ESI† and manuscript.

#### Author contributions

PKK discovered /conceptualized the initial project. Kulbir carried out most of the experiments and gathered the data. PKK, SG & TD helped in interpreting the experimental results. SCS, Kulbir & SD worked on growing the crystals and recording the crystallographic data. Kulbir and SD write the first draft of the article. PKK & TD have corrected the manuscript, finalized the final draft, and guided during the revision. PKK followed and guided the whole project work.

### Conflicts of interest

There are no conflicts to declare.

### Acknowledgements
