# Fluorinated vs. non-fluorinated tetrahedral Tri<sup>4</sup>Tri<sup>4</sup> porous organic cages for H<sub>2</sub>, CO<sub>2</sub>, and CH<sub>4</sub> adsorption†

Tim David, Da Robert Oestreich, Db Tobias Pausch, Da Yuki Wada, Dc Tom Fleck-Kunde, Da Masaki Kawano, Dc Christoph Janiak Db and Bernd M. Schmidt D\*

We present the synthesis of two porous complementary tetrahedral Tri<sup>4</sup>Tri<sup>4</sup> imine cages, exhibiting Brunauer-Emmett-Teller (BET) surface areas of 591 m<sup>2</sup> g<sup>-1</sup> and 753 m<sup>2</sup> g<sup>-1</sup>, suitable for the adsorption of H<sub>2</sub>, CO<sub>2</sub>, and CH<sub>4</sub>. Comparisons in terms of crystallinity, thermal stability, porosity, and selectivity highlight the promising properties of fluorinated and non-fluorinated porous organic cages as functional materials.

Harnessing the power of organic synthesis in combination with subcomponent self-assembly of small and rigid building blocks into larger assemblies under thermodynamic control gives facile access to novel materials by molecular design. Besides metalorganic frameworks (MOFs) and covalent organic frameworks (COFs), porous organic cages (POCs) are an emerging class of porous materials that are self-assembled in solution before precipitation as solid materials.<sup>2</sup> These discrete, three-dimensional molecular assemblies differ from networks by enabling straightforward solution-phase processing and analysis while also allowing post-synthetic transformations that can modify the scaffolds with atomic precision.<sup>2,3</sup> Dynamic covalent chemistry, particularly imine bond condensation<sup>4</sup> and boronate ester formation, <sup>2a,b,e</sup> among others, <sup>2e</sup> can be employed to access POCs. In comparison to imine cages, the rigidity of boronate ester linkages is beneficial for the synthesis of large shape-persistent cages, <sup>2d-f</sup> as shown by Mastalerz and co-workers, who reported a giant boronate ester cage with cuboctahedral symmetry exhibiting an extraordinarily

Herein, we present the synthesis of two highly porous Tri4Tri4 imine cages, Et4H4 and Et4F4. When reacting the preorganised 1,3,5-tris(aminomethyl)-2,4,6-triethylbenzene (Et) with the non-fluorinated trialdehyde (H) and the analogous highly fluorinated trialdehyde (F), Et<sup>4</sup>H<sup>4</sup> and Et<sup>4</sup>F<sup>4</sup> form, respectively, opening up the possibility to investigate the influence of fluorinated units in porous organic materials (Fig. 1a). Heating the building blocks in a chloroform/methanol (3:1) mixture at 60 °C without stirring results in the growth of cube-like crystals on the walls of the reaction vessel. Repeated solvent exchange against npentane and drying of the crystals in air gives Et4H4 in 84% and Et<sup>4</sup>F<sup>4</sup> in 45% yield as colourless crystals (Fig. S9–S14, ESI†). The <sup>1</sup>H NMR analysis of the redissolved crystals shows sharp signals, indicating the clean formation of both cages (Fig. 1b). Furthermore, <sup>19</sup>F NMR analysis of Et<sup>4</sup>F<sup>4</sup> reveals only one broad signal for the two independent aromatic fluorine atoms (Fig. S44, ESI†). Size determination using <sup>1</sup>H DOSY experiments gives solvodynamic radii of  $r_{\text{solv}} = 1.04 \text{ nm} (D = 3.98 \times 10^{-10} \text{ m}^2 \text{ s}^{-1} \text{ in CDCl}_3) \text{ for Et}^4 \text{H}^4$ and  $r_{\text{soly}} = 1.24 \text{ nm}$  (D = 3.35 × 10<sup>-10</sup> m<sup>2</sup> s<sup>-1</sup> in CDCl<sub>3</sub>) for Et<sup>4</sup>F<sup>4</sup>, respectively (Fig. S1-S4, ESI†). Crystals suitable for single-crystal Xray diffraction (SC-XRD) analysis can be obtained directly from the reaction mixture and reveal the cubic space groups F43c for Et4H4

high surface area of  $SA_{BET} = 3758 \text{ m}^2 \text{ g}^{-1}$  already in 2014, comparable to those observed for extended networks like MOFs and COFs.5 The group of Beuerle recently reported the first water-stable boronate ester cage,6 stable under ambient conditions with a welldefined microporous solid state structure (SA<sub>BET</sub> = 2534 m<sup>2</sup> g<sup>-1</sup>), paving the way for further applications of dynamic covalent boronate ester materials. In addition, the use of computational crystal structure prediction,8 along with computational design in supramolecular synthesis at both the molecular level and in the solid state,9 has been key to obtaining a complex, shape-persistent [4[2+3]+6] cage by reversible nucleophilic aromatic substitution. 10 From the various accessible cage structures, the class of  ${
m Tri}^4{
m Tri}^4$  cages surprisingly remains largely underrepresented. Despite their tetrahedral structure enabling the formation of three-dimensional pores, only a few porous cages have been reported to date. 9,11a-c,12

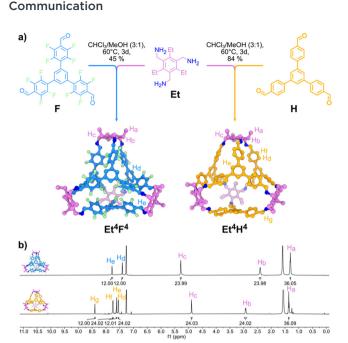

Fig. 1 (a) Synthesis of crystalline  ${\rm Et^4F^4}$  and  ${\rm Et^4F^4}$  by combining H and F with 1.20 eq. Et, respectively; (b)  $^1{\rm H}$  NMR spectra of  ${\rm Et^4F^4}$  and  ${\rm Et^4H^4}$  recorded in CDCl<sub>3</sub> at 25 °C.

and Fd3 for Et4F4. Et4F4 assembles in a face-to-face arrangement with centroid-to-centroid distances of 4.5 Å for the fluorinated tetraphenyl panels packing loosely and C-H···F contacts between the inner fluorine and the hydrogen of the phenyl core of a neighbouring cage's panel with a distance of 3.1 Å, resulting in interconnected windows and a three-dimensional pore network (Fig. S6, ESI†). Additional vertex-to-vertex arrangements of Et from four separate cages lead to isolated extrinsic pores that are inaccessible. In contrast, Et<sup>4</sup>H<sup>4</sup> packs in a close window-towindow arrangement but also exhibits an extensively connected three-dimensional pore network. Powder X-ray diffraction (PXRD) analysis of dried cage crystals shows sharp diffraction for Et<sup>4</sup>F<sup>4</sup>, revealing a partly crystalline material before and after all gas sorption experiments (Fig. 2a). Whereas the PXRD analysis of Et<sup>4</sup>H<sup>4</sup> shows broad diffraction, indicating the formation of a largely amorphous material upon activation (Fig. 2a). Additional thermogravimetric analysis shows a high thermal stability for both materials, with decomposition temperatures of 348 °C for Et<sup>4</sup>F<sup>4</sup> and 352 °C for Et<sup>4</sup>H<sup>4</sup>, respectively (Fig. S21 and S22, ESI†). Et<sup>4</sup>F<sup>4</sup>'s seemingly more robust networked cages and high thermal stability are most likely the result of several stabilising weak interactions between the fluorinated and (non-)fluorinated parts of the cages in the highly symmetric lattice. 13 Jiang et al. outlined the improved crystallinity of fluorine-containing systems due to self-complementary electronic interactions between fluorinated and non-fluorinated counterparts. 14,15 The pore sizes of Et4H range from 5.6 Å to 11.7 Å, derived from the SC-XRD data. Analogues are the diameters 3.4 Å and 6.4 Å for Et<sup>4</sup>F<sup>4</sup>, respectively. Non-local density functional theory (NLDFT) and grand canonical Monte Carlo (GCMC) calculations based on the N2 sorption isotherms at 77 K also show the smaller pore size of Et<sup>4</sup>F<sup>4</sup> with a narrow pore size distribution around 5.8 Å (Fig. S29,

ESI†). Contrarily, the pore size distribution of Et<sup>4</sup>H<sup>4</sup> shows a broader maximum for micropores around 14 Å and some mesopores with pore diameters between 20 Å and 80 Å, which are larger than the cage compounds themselves (Fig. S26, ESI†), indicating cracks and a subsequent loss of crystallinity. This suggests that the solvent exchange and subsequent drying of the crystals obtained from the reaction mixture, in contrast to Et<sup>4</sup>F<sup>4</sup>, leads to a loss of crystallinity for Et<sup>4</sup>H<sup>4</sup>. The observed porosity of Et<sup>4</sup>H<sup>4</sup>, however, is suggested to be caused by the cage's large voids in the amorphous material. The pore widths of both cages and the kinetic diameters of H<sub>2</sub> (2.89 Å), CO<sub>2</sub> (3.30 Å), and CH<sub>4</sub> (3.80 Å) indicate that both should be suitable for the adsorption of these gases. 16 Therefore, the dried crystals were activated by heating under dynamic vacuum overnight, at 80 °C for Et<sup>4</sup>F<sup>4</sup> and at 140 °C for Et<sup>4</sup>H<sup>4</sup>. Between the measurements, both samples were recycled by heating to 80 °C for two hours in vacuo. The obtained specific surface areas (SA) of 591 m<sup>2</sup> g<sup>-1</sup> and 753 m<sup>2</sup> g<sup>-1</sup> for  $Et^4F^4$  and  $Et^4H^4$ , respectively, determined by the BET method, are comparable to the Tri<sup>4</sup>Di<sup>6</sup> cage CC3 (SA<sub>BET</sub> = 624 m<sup>2</sup> g<sup>-1</sup>) and a Tri<sup>2</sup>Di<sup>3</sup> exo-functionalised salicylimine cage  $(SA_{BET} = 744 \text{ m}^2 \text{ g}^{-1})$  of similar sizes.<sup>17,18</sup> To the best of our knowledge, Et4F4 and Et4H4 exhibit among the largest specific surface areas reported for tetrahedral Tri4Tri4 cages. Et4F4 is additionally the largest fluorinated Tri4Tri4 imine cage, surpassing cage FC1 ( $SA_{BET} = 536 \text{ m}^2 \text{ g}^{-1}$ ) previously published by our group. <sup>12</sup> The pore volume of both cages was determined from the N2 sorption isotherms at 77 K by GCMC as well as NLDFT calculations, revealing a total pore volume of 0.39 cm<sup>3</sup> g<sup>-1</sup> and a micropore volume of 0.21 cm<sup>3</sup> g<sup>-1</sup> for Et<sup>4</sup>F<sup>4</sup> and 0.59 cm<sup>3</sup> g<sup>-1</sup> and 0.24 cm<sup>3</sup> g<sup>-1</sup> for Et<sup>4</sup>H<sup>4</sup>, respectively. The Et<sup>4</sup>H<sup>4</sup> cage adsorbs 14.5 mmol  $g^{-1}$  (28.9 wt%) of N<sub>2</sub> at 77 K and  $0.95p/p_0$  (Fig. 2c), as beyond this relative pressure, N2 condensation inside the pore network can be observed, which is often not considered. This is comparable to the adsorption performance of the substituted Tri4Di6 cages reported by Mastalerz et al., which also remain porous in their amorphous state while exhibiting specific surface areas ranging from 690 to 727 m<sup>2</sup> g<sup>-1</sup>, with N<sub>2</sub> uptake values between 17.4 and 21.4 mmol  $g^{-1}$  at 77 K and  $0.95p/p_0$  bar. <sup>19</sup> The  $N_2$ sorption isotherm of Et4H4 can be classified as a combination of type-Ib (low  $p/p_0$  for the microporous region) and a type-II isotherm (higher  $p/p_0$ , macroporous multi-layer region) with a wide H4 hysteresis loop.20 Et4F4 exhibits a higher gas uptake of 10.1 mmol g<sup>-1</sup> (22.0 wt%) N<sub>2</sub> at 77 K and  $0.95p/p_0$  (Fig. 2c), compared to the slightly larger CC3 (8.2 mmol g<sup>-1</sup>, 18.6 wt%, 1 bar). 17 The N2 adsorption isotherm can again be described as a combination of a type-I and type-II isotherm with a H4 hysteresis loop. Noteworthy is the step in the H4 hysteresis loop at  $0.5p/p_0$ , more clearly seen in Et<sup>4</sup>F<sup>4</sup> than in Et<sup>4</sup>H<sup>4</sup>, which we assign to two types of bottle-neck pores in combination with framework reconstruction.<sup>20</sup> Exhibiting a hydrogen uptake of 6.1 mmol g<sup>-1</sup> (1.2 wt%), Et<sup>4</sup>H<sup>4</sup> adsorbs more H<sub>2</sub> at 77 K and 1 bar than the almost twice as large Tri4Di6 tert-butyl substituted adamantoid cage ( $SA_{BET} = 1377 \text{ m}^2 \text{ g}^{-1}$ , 5.6 mmol  $\text{g}^{-1}$ ) and is also comparable to the smaller sized CC2 ( $SA_{BET} = 533 \text{ m}^2 \text{ g}^{-1}$ , 5.9 mmol  $\text{g}^{-1}$ ) and CC3 (SA<sub>BET</sub> = 624 m<sup>2</sup> g<sup>-1</sup>, 5.0 mmol g<sup>-1</sup>) POCs reported.<sup>17,21</sup> We further measured an adsorption of 3.0 mmol g<sup>-1</sup> (11.8 wt%) for

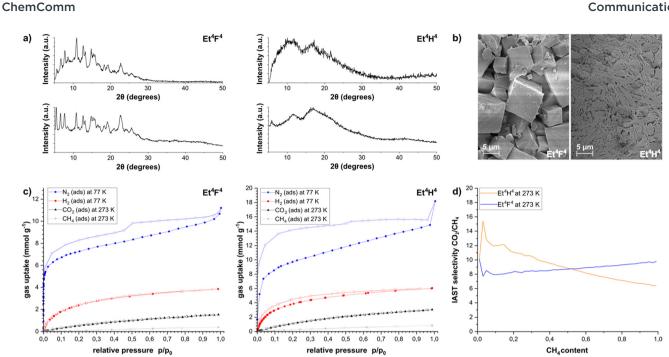

Fig. 2 (a) Powder X-ray diffraction (PXRD) patterns before (bottom) and after (top) sorption experiments of Et<sup>4</sup>F<sup>4</sup> (left) and Et<sup>4</sup>H<sup>4</sup> (right); (b) true to scale cutouts from scanning electron microscope (SEM) images of Et<sup>4</sup>F<sup>4</sup> (left) and Et<sup>4</sup>H<sup>4</sup> (right), scanning voltage 5 kV; (c) gas adsorption (filled) and desorption (hollow) overview of Et<sup>4</sup>F<sup>4</sup> (left) and Et<sup>4</sup>H<sup>4</sup> (right); (d) ideal adsorbed solution theory (IAST) selectivity curves of Et<sup>4</sup>F<sup>4</sup> (orange) and Et<sup>4</sup>H<sup>4</sup> (blue) for varying gas compositions of CO<sub>2</sub>/CH<sub>4</sub> (1 bar total pressure, 273 K).

CO<sub>2</sub> at 273 K and 1 bar. This value is again well comparable with the cages mentioned above showing CO<sub>2</sub> uptakes of 2.7 mmol g<sup>-1</sup> (11.8 wt%), 3.0 mmol g<sup>-1</sup> (11.7 wt%), and 2.5 mmol g<sup>-1</sup> (9.9 wt%), respectively. 17,22 For CH4, we measured a low gas uptake at 273 K and 1 bar of 0.8 mmol g<sup>-1</sup> (1.3 wt%) compared to CC2  $(1.1 \text{ mmol } g^{-1}, 1.7 \text{ wt\%}) \text{ and } CC3 (1.5 \text{ mmol } g^{-1}, 2.3 \text{ wt\%}),$ resulting in a higher selectivity of 10.3:1 (w/w) for CO<sub>2</sub> over CH<sub>4</sub>, which is well comparable to the selectivity of 10:1 (w/w) for the adamantoid cage by Mastalerz et al. 17,21 The measured gas adsorptions of the highly fluorinated Et4F4 are much lower than for the non-fluorinated Et4H4. Et4F4 adsorbs at 1 bar 3.9 mmol g-1  $(0.8 \text{ wt\%}) \text{ H}_2 (77 \text{ K}), 1.5 \text{ mmol g}^{-1} (6.3 \text{ wt\%}) \text{ CO}_2 (273 \text{ K}), \text{ and}$  $0.4 \text{ mmol g}^{-1}$  (0.6 wt%) CH<sub>4</sub> (273 K). The smaller, previously reported cage FC1 exhibits higher adsorption properties for H2  $(7.5 \text{ mmol g}^{-1} \text{ and } 1.5 \text{ wt}\%) \text{ and } CO_2 (4.2 \text{ mmol g}^{-1} \text{ and } 19.0 \text{ wt}\%)$ than both here reported cages. 12 To date, FC1 is the cage with the highest CO<sub>2</sub> uptake ever reported for POCs. 10 When calculating the gas uptake for a porous material in moles of gas per gramme material, the molecular weight and density of the material are not taken into account. This entails that smaller cages, such as FC1 (1309 g mol<sup>-1</sup>), frequently display higher gas uptakes since there are essentially more cage molecules with specific surface area per gramme of material available. To evaluate the quantitative uptake, we also calculated the gas uptake in moles of gas per mole of cage and volume of adsorbed gas per volume of the cage (Tables S3-S5, ESI†). For CO<sub>2</sub>, we calculated gas uptakes of 5.5 mol mol<sup>-1</sup> for FC1 and 4.9 mol mol<sup>-1</sup> together with 7.1 mol mol<sup>-1</sup> for Et<sup>4</sup>F<sup>4</sup> and Et<sup>4</sup>H<sup>4</sup>, respectively. In this regard, Et<sup>4</sup>H<sup>4</sup> is the superior adsorbent material in direct comparison to FC1. With increasing pore sizes, the number of adsorbed gas molecules that directly interact with

the surface area becomes less, and therefore higher relative pressure is needed for the pore filling through multilayer adsorption by adsorbate-adsorbate interactions to achieve a higher gas uptake. However, besides adsorption capacity, selectivity is arguably another critical property of a porous material for industrial applications such as gas purification.<sup>23</sup> Natural gas, primarily composed of CH4, is a crucial energy source that is often contaminated with over 40% N2 and CO2, which must be removed before combustion.<sup>24</sup> Therefore, we calculated the ideal adsorbed solution theory (IAST) selectivity for CO2 over CH4, based on the sorption isotherms at 273 K and 1 bar (Fig. 2d). For a 1:1 CO2: CH4 composition, both cages exhibit nearly the same selectivity (8.80 and 8.71 for Et4H4 and Et4F4, respectively). With decreasing CO<sub>2</sub> content, the selectivity of the non-fluorinated cage decreases to 6.6 at 95% CH<sub>4</sub> in the gas composition, whereas the selectivity of the fluorinated cage increases to 9.7 for the identical composition (Fig. 2d). In addition to the recent studies of our group, Miljanić et al. reported the higher selectivity of fluorinated covalent triazine frameworks to CO2 in a CH4-enriched composition and the higher CO<sub>2</sub>-phillicity of fluorine-containing materials, resulting from attractive quadrupole interactions. 12,13b The better selectivity of Et<sup>4</sup>F<sup>4</sup>, especially in CH<sub>4</sub>-enriched compositions ( $\geq$ 60%), shows the potential for the application of fluorinated materials in the purification of gases.

In conclusion, we presented the successful synthesis and characterisation of two new porous Tri4Tri4 imine cages, Et4H4 and the highly fluorinated Et<sup>4</sup>F<sup>4</sup>. To the best of our knowledge, both cages are among the largest shape-persistent cages within this topology. 11a-c,12 We further investigated the influence of the incorporation of highly fluorinated building blocks into

Communication ChemComm

porous materials in terms of retention of crystallinity, thermal stability, porosity, selectivity, and reusability. The fluorinated Et<sup>4</sup>F<sup>4</sup> shows a much higher retention of the crystallinity, whereas Et<sup>4</sup>H<sup>4</sup> was obtained as an amorphous material upon solvent removal. Both materials exhibit high thermal stability of approximately 350 °C and gas adsorption measurements further demonstrated that both cages are highly porous with BET surface areas of 591 m<sup>2</sup> g<sup>-1</sup> ( $Et^4F^4$ ) and 753 m<sup>2</sup> g<sup>-1</sup> ( $Et^4H^4$ ), which are accessible for the uptake of H2 and CO2, simultaneously showing a low affinity towards CH<sub>4</sub>. At 273 K and 1 bar, both cages nearly exhibit the same IAST selectivity for CO<sub>2</sub> over CH<sub>4</sub> for a 1:1 composition of the gases of 8.8 and 8.7 for Et<sup>4</sup>H<sup>4</sup> and Et<sup>4</sup>F<sup>4</sup>, respectively. For compositions with decreasing amounts of CO2, the selectivity for CO2 of the non-fluorinated cage decreases, whereas the selectivity of the fluorinated cage increases, demonstrating the advantages of fluorine-containing building blocks in materials for gas purification. Unveiling significant relationships between the structural and electronic differences of fluorinated and non-fluorinated building blocks, offering new ways to tailor highly selective porous organic architectures for advanced functional materials.
