Bromoargentate/g-C₃N₄ heterojunction by *in situ* growth: 2-D bromoargentate framework with a transition metal complex linker and cocatalyst for enhanced photocatalytic activity *via* g-C₃N₄ hybrid[†]

Yiming Tian, Taohong Ren, Hongjin Zhu and Dingxian Jia ^{*}

A 2-D bromoargentate hybrid $[(\text{Cu}(\text{phen}))_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ (phen = 1,10-phenanthroline) (**1**) was prepared by the reaction of $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, AgBr, KBr and phen in a $\text{C}_2\text{H}_5\text{OH}/\text{DMF}$ mixed solvent under solvothermal conditions. In compound **1**, three tetrahedral AgBr_4 units are interconnected into a 1-D $[\text{Ag}_3\text{Br}_5]_n$ chain by edge-sharing. The $[\text{Ag}_3\text{Br}_5]_n$ chains were linked by tetranuclear $[(\text{Cu}(\text{phen}))_2(\mu\text{-OH})_2]_2$ complex units *via* Cu–Br bonds to form the layered bromoargentate hybrid $[(\text{Cu}(\text{phen}))_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$. The $[(\text{Cu}(\text{phen}))_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layers were successfully loaded on the surface of g-C₃N₄ by *in situ* growth under the same solvothermal conditions, and a 1/g-C₃N₄ heterojunction was formed. The 1/g-C₃N₄ heterojunction exhibited a stable and reproducible photocurrent response with a photocurrent density of 23.68 $\mu\text{A cm}^{-2}$, which is 2.65 and 8.05 times greater than those of parent **1** and g-C₃N₄, respectively. The degradation conversion of crystal violet (CV) reached 98.0% on the photocatalyst of 1/g-C₃N₄ heterojunction after light irradiation for 60 min. The 1/g-C₃N₄ heterojunction exhibited a much higher photocatalytic efficiency than did **1** and g-C₃N₄ for CV degradation, which suggested that the synergistic effect between **1** and g-C₃N₄ in the heterojunction promoted photocatalytic performance. The investigation of the catalytic mechanism showed that all h^+ , $\cdot\text{OH}$ and $\cdot\text{O}_2^-$ species are reactive substances in the photodegradation.

Introduction

The environmental pollution caused by wastewater has attracted widespread attention due to the increasing amount of organic pollutants, such as organic dyes, antibiotics, and pesticides discharged into water, with an increasing population and industrialization.¹ Organic pollutants might have a series of harmful impacts on the environment and human health due to their chemical toxicity and nonbiodegradability. To meet the need for clean and safe water, various wastewater treatment technologies, such as screening, filtration, and centrifugal separation, are conventionally used.² Currently, there is increasing interest in using photocatalytic techniques to

eliminate organic pollutants in wastewater. Photocatalytic degradation is an environmentally friendly and economical wastewater treatment method, in which sunlight energy is used to convert organic pollutants into small molecules or nontoxic substances.³ In recent years, organic-inorganic halometallate hybrid materials, especially iodoargentate hybrids, have been promising candidate photocatalysts for the degradation of organic pollutants in wastewater treatment. The polymeric iodoargentate hybrids $(\text{EtPPH}_3)\text{Ag}_3\text{I}_4$ (Et = ethyl), $(n\text{-PrPPH}_3)\text{Ag}_3\text{I}_4$ ($n\text{-Pr}$ = n -propyl), $(i\text{-PrPPH}_3)\text{Ag}_5\text{I}_6$ ($i\text{-Pr}$ = isopropyl), and $[(\text{Me})_2\text{-}2,2'\text{-bipy}]\text{Ag}_8\text{I}_{10}$ (Me = methyl, 2,2'-bipy = 2,2'-bipyridine) exhibited photocatalytic efficiencies for the degradation of the organic dyes rhodamine B (RhB) and methyl orange (MO) in wastewater under visible light irradiation.^{4,5} The TM-complexes containing iodoargentate hybrids, $\text{K}_x[\text{TM}(2,2'\text{-bipy})_3]_2\text{Ag}_6\text{I}_{11}$ (TM = Fe, Co, Ni, Zn; $x = 0.89\text{--}1$), $[\text{Ni}(2,2'\text{-bipy})_3][\text{H-}2,2'\text{-bipy}]\text{Ag}_6\text{I}_6$, $[\text{TM}(\text{phen})_3]_2\text{Ag}_{11}\text{I}_{15} \cdot \text{H}_2\text{O}$ (phen = 1,10-phenanthroline) (TM = Co, Cu), and $[\text{TM}(\text{phen})_3]_2\text{Ag}_{13}\text{I}_{17}$ (TM = Co, Cd) were photocatalytically active in the degradation of crystal violet (CV) and RhB.^{6,7} The degradation conversions of CV reached 56–92% after 60 min of visible light irradiation, while the degradation conversions of RhB were in the range of 29–80% after 180 min of light irradiation. The photocatalytic activities of halometallate

hybrids are affected by various factors, such as the composition, structure, optical bandgap, and electron-accepting ability of counter cations.^{7,8} The compositions and structures of halometallate hybrid materials are influenced by various factors during preparation, such as the features and charge distributions of counter cations, ligands to the metal centers, and guest solvent molecules.⁹ A large number of iodoargentate hybrids with different compositions and structures have been prepared using organic cations, transition metal (TM), and lanthanide (Ln) metal complex cations as counter cations or structural directing agents.^{10–12} However, the photocatalytic activity and stability of the iodoargentate hybrid materials need to be enhanced for the purpose of application.

Since the 2-D polymeric semiconductor $g\text{-C}_3\text{N}_4$ (graphitic carbon nitride) was used as a metal-free conjugated photocatalyst for H_2 evolution in 2006,¹³ $g\text{-C}_3\text{N}_4$ has been considered a next-generation semiconductor photocatalyst due to its unique triazine ring structure, tunable band gap (normal band gap of ~ 2.7 eV), high physicochemical stability, excellent photoelectrochemical properties, and low cost.¹⁴ $g\text{-C}_3\text{N}_4$ can be easily prepared by the thermal polycondensation of several inexpensive precursors, such as cyanamide, dicyandiamide, melamine, urea, thiourea, and ammonium thiocyanate.^{14c,15} As a 2-D polymeric semiconductor, $g\text{-C}_3\text{N}_4$ can construct various cocatalysts with well-matched energy levels of other semiconductors to form heterostructures. Many $g\text{-C}_3\text{N}_4$ -based composites with different components and compositions have been prepared by loading metals,¹⁶ metal oxides,¹⁷ or metal sulfides¹⁸ on the surface of $g\text{-C}_3\text{N}_4$ layers. In recent years, the synthesis of $g\text{-C}_3\text{N}_4$ -based semiconductor cocatalysts by loading metal organic frameworks (MOFs) has attracted increasing interest.¹⁹ Yue prepared a Ni-MOF-based nanocomposite of UNiMOF/ $g\text{-C}_3\text{N}_4$, which exhibited enhanced photocatalytic H_2 production under visible light irradiation.²⁰ Lu and Zolfigol constructed Ti-MOF/ $g\text{-C}_3\text{N}_4$, and Zr-MOF/ $g\text{-C}_3\text{N}_4$ heterojunctions for the photocatalysis of the coupling of primary amines and the Gomberg–Bachmann–Hey reaction.²¹ Very recently, we prepared a $g\text{-C}_3\text{N}_4$ /[Pb(18-crown-6)(PbAg₂I₆)]_n (18-crown-6 = 1,4,7,10,13,16-hexaoxacyclooctadecane) heterocomposite by doping the layered heterometallic Pb-iodoargentate hybrid [Pb(18-crown-6)(PbAg₂I₆)]_n with $g\text{-C}_3\text{N}_4$.²² The heterocomposite exhibited synergistically enhanced photocatalytic activity for MB degradation. In this work, we designed and synthesized a layered bromoargentate [$\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)\}_n$ (**1**), and prepared the first $g\text{-C}_3\text{N}_4$ /bromoargentate heterojunction of $1/g\text{-C}_3\text{N}_4$ by loading the [$\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)\}_n$ layer on the surface of $g\text{-C}_3\text{N}_4$ via an *in situ* growth method. The photoelectric and photocatalytic properties of the $1/g\text{-C}_3\text{N}_4$ heterojunction were investigated.

Results and discussion

Syntheses

Crystals of **1** suitable for X-ray single-crystal structure measurements were obtained by the reaction of $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, AgBr, KBr and phen in a $\text{C}_2\text{H}_5\text{OH}/\text{DMF}$ mixed solvent under

solvothetical conditions. The same reaction in the sole $\text{C}_2\text{H}_5\text{OH}$ solvent failed to produce compound **1**, indicating that DMF played an important role in the crystallization of compound **1**. In the FT-IR spectra of **1**, the absorption bands at 2800–2900 cm^{-1} are attributed to C–H vibrations. The bands at approximately 1580–1520 cm^{-1} are due to the stretching vibrations of the C=N bond (Fig. S1†). The wide bands at 3578 (m) and 3447 (s) in **1** are attributed to the vibrations of the O–H bonds involved in hydrogen bonding. The PXRD patterns of as-prepared **1** are consistent with the simulated XRD patterns based on the single-crystal XRD data (Fig. 1), indicating that the bulk phase of as-prepared compound **1** was pure. The $1/g\text{-C}_3\text{N}_4$ heterojunction was prepared *in situ* by synthesis of **1** in the presence of $g\text{-C}_3\text{N}_4$ powder. In the FT-IR spectrum of the $1/g\text{-C}_3\text{N}_4$ heterojunction, the absorption peaks at 805, 1233, 1314, 1395, and 1626 cm^{-1} are attributed to the typical stretching mode for the CN-heterocyclic system of $g\text{-C}_3\text{N}_4$,^{18a,23} while the main absorption bands of **1** are almost unchanged (Fig. S1†). A broad peak at 27.3° appeared in the PXRD pattern of the $1/g\text{-C}_3\text{N}_4$ heterojunction, which was indexed as the characteristic peak of $g\text{-C}_3\text{N}_4$,^{18a,23,24} while the peak positions of **1** were unchanged (Fig. 1). SEM images of the as-prepared $g\text{-C}_3\text{N}_4$ and $1/g\text{-C}_3\text{N}_4$ heterojunction are shown in Fig. 2. The $g\text{-C}_3\text{N}_4$ has an irregular laminar structure with frilled and wrinkled sheets on its surface (Fig. 2a). The $1/g\text{-C}_3\text{N}_4$ heterojunction micrographs exhibited distribution and deposition of **1** rod-like microcrystals on the surface of the $g\text{-C}_3\text{N}_4$ nanosheets (Fig. 2b and c). EDS analysis revealed the presence of C, N, O, Br, Cu and Ag in the obtained $1/g\text{-C}_3\text{N}_4$ heterojunction (Fig. 2d), confirming the coexistence of **1** and $g\text{-C}_3\text{N}_4$. The results of FT-IR, PXRD, SEM and EDS measurements confirmed that the $1/g\text{-C}_3\text{N}_4$ heterojunction was successfully prepared by *in situ* growth under solvothetical conditions.

Crystal structure of **1**

Compound **1** crystallizes in the triclinic space group $P\bar{1}$ with two formula units in the unit cell (Table S1†). Its asymmetric unit is composed of three Ag, five Br and two Cu atoms, two phen molecules, and two OH groups (Fig. 3a). All the Ag atoms

Fig. 1 Simulated XRD pattern of **1**, and experimental powder XRD patterns of as-prepared **1**, $g\text{-C}_3\text{N}_4$, and $1/g\text{-C}_3\text{N}_4$ heterojunction.

Fig. 2 SEM images of $g\text{-C}_3\text{N}_4$ (a) and $1/g\text{-C}_3\text{N}_4$ (b and c), and EDS spectrum of $1/g\text{-C}_3\text{N}_4$ (d).

are coordinated by four Br atoms to form the primary building unit (PBU) AgBr_4 . Three AgBr_4 PBUs are interlinked by edge-sharing to form the secondary building unit (SBU) Ag_3Br_7 with a semi-cubic core Ag_3Br_4 , in which three Ag atoms are capped by a $\mu_3\text{-Br}$ triple ligand (Fig. 3b). The Ag_3Br_7 SBUs are connected into a one-dimensional $[\text{Ag}_3\text{Br}_5]_n$ chain (Fig. 3c). In the $[\text{Ag}_3\text{Br}_5]_n$ chain, $\text{Ag}\cdots\text{Ag}$ metal-metal interaction is observed between $\text{Ag}(3)$ and $\text{Ag}(3\#1)$ with a $\text{Ag}\cdots\text{Ag}$ separation of $3.0726(15)$ Å (Table S2[†]), which was consistent with those found in reported bromoargentate hybrids.^{25a,26} All AgBr_4 PBUs had distorted tetrahedral geometries with Br-Ag-Br angles in the range of $94.51(3)$ – $134.96(5)^\circ$ (Table S2[†]). The Ag-Br bond lengths vary from $2.5827(11)$ Å to $2.8415(13)$ Å, and are consistent with those of the 1-D chains $[\text{Ag}_2\text{Br}_3]_n^{n-}$,²⁷ $[\text{Ag}_6\text{Br}_{11}]_n^{5n-}$, $[\text{Ag}_{13}\text{Br}_{17}]_n^{4n-}$.^{8a} The $\text{Cu}^{2+}(1)$ and $\text{Cu}^{2+}(2)$ ions are joined by two $\mu\text{-OH}$ bridging ligands and each Cu^{2+} ion is coordinated by a bidentate phen to form a $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2]$ unit (Fig. 3a). Two $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2]$ units are coupled by sharing the O2 atom to yield a tetranuclear $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2]_2$ complex unit (Fig. 4). The $\text{Cu}(1)$ atom is further coordinated by a Br atom from the $[\text{Ag}_3\text{Br}_5]_n$ chains (Fig. 3a). As a result, acting as bridging linkers, the $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2]_2$ complex units connect the $[\text{Ag}_3\text{Br}_5]_n$ chains into a $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layer *via* $\text{Cu}(1)\text{-Br}(1)$ (Fig. 5). Both the $\text{Cu}^{2+}(1)$ and $\text{Cu}^{2+}(2)$ ions have distorted tetragonal pyramid geometries with the $\text{O}_2\text{N}_2\text{Br}$ and O_3N_2 donor sets, respectively (Fig. 3d and e). The axial angles of the tetragonal pyramids are $161.3(2)^\circ$ and $172.7(3)^\circ$ for $\text{Cu}(1)\text{O}_2\text{N}_2\text{Br}$, and $164.9(3)^\circ$ and $177.0(3)^\circ$ for $\text{Cu}(2)\text{O}_3\text{N}_2$ (Table S2[†]). The Cu-Br , Cu-N , and Cu-O bond lengths are $2.9264(13)$ Å, $1.996(7)$ – $2.024(6)$ Å and $1.919(5)$ – $2.381(5)$ Å, respectively (Table S2[†]), which are consistent with the corresponding bond lengths reported in the literature.²⁵ The $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layers are perpendicular to the a axis of the unit cell. The planes of all the phen molecules are parallel, and the interplanar separations between the centroids of the phen molecules are in the range of 3.471 – 3.560 Å, indicating weak intermolecular $\pi\cdots\pi$ stacking interactions between the $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layers (Fig. S2[†]). The interplane separations are in the range of those of reported metal complexes with phen ligands.²⁸ The phen ligands further interact with the $[\text{Ag}_3\text{Br}_5]_n$ chains in neighboring $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layers through $\text{C-H}\cdots\text{Br}$ hydrogen bonds (Fig. S3[†]). The $\text{C}\cdots\text{Br}$ distances are in the range of 3.461 – 3.847 Å (Table S3[†]), which are consistent with those reported in organic bromoargentate hybrids.^{7,29} The $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layers are connected into a 3-D framework *via* the $\pi\cdots\pi$ and $\text{C-H}\cdots\text{Br}$ interactions.

Several bromoargentate hybrids that contain transition metal complex cations with phen or 2,2'-bipy organic ligands have been prepared and structurally characterized.^{8a,25a} In these hybrids, the coordination sites of TM^{2+} ions are saturated by three phen or 2,2'-bipy ligands, and the bromoargentate aggregates cannot coordinate to the TM^{2+} ions. Examples include $\text{K}[\text{TM}(2,2'\text{-bipy})_3]_2\text{Ag}_6\text{Br}_{11}$ ($\text{TM} = \text{Fe}, \text{Co}, \text{Ni}, \text{Zn}$), $[\text{TM}(2,2'\text{-bipy})_3]_2\text{Ag}_{13}\text{Br}_{17}$,^{8a} $[\text{TM}(\text{phen})_3]_2\text{Ag}_{13}\text{-Br}_{17}\cdot 2\text{DMSO}\cdot 3\text{H}_2\text{O}$ ($\text{TM} = \text{Fe}, \text{Co}, \text{Ni}$), $[\text{Cu}(\text{phen})_2(\text{Br})]\text{AgBr}_2$, and $[\text{Fe}(\text{phen})_3]\text{Ag}_2\text{Br}_4\cdot\text{DMF}$.^{25a} In compound **1**, the $\text{Cu}(1)^{2+}$ ion forms a 4-coordinated center in the $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2]_2$ complex units, thus, the $[\text{Ag}_3\text{Br}_5]^{2-}$ anion can bind to the $\text{Cu}(1)^{2+}$ center *via* the $\text{Br}(1)$ atom to satisfy the coordination number 5 for the Cu^{2+} ion. Compound **1** represents the first example of a bromoargentate hybrid with a bromoargentate anion coordinating to the TM center *via* a TM-Br bond.

Fig. 3 Structural diagrams of **1**: asymmetric unit $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]$ of **1** with the labelling scheme (a), the trinuclear secondary building unit Ag_3Br_7 (b), the $[\text{Ag}_3\text{Br}_5]_n$ chain (c), and the tetragonal pyramid of $\text{Cu}(1)\text{O}_2\text{N}_2\text{Br}$ (d) and $\text{Cu}(2)\text{O}_3\text{N}_2$ (e).

Fig. 5 Structural diagrams of **1**: the $[(\text{Cu}(\text{phen}))_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layer in **1** viewed along the a axis (a), and the $\mu\text{-}[(\text{Cu}(\text{phen}))_2(\mu\text{-OH})_2]_2$ linkers between the $[\text{Ag}_3\text{Br}_5]_n$ chains (b). The carbon and hydrogen atoms in (a) are omitted for clarity. Yellow tetrahedra: AgBr_4 . Cyan tetragonal pyramids: $\text{CuO}_2\text{N}_2\text{Br}$ and CuO_3N_2 .

Optical bandgaps and photocurrent responses

Solid state UV-vis-NIR reflectance spectra of the $g\text{-C}_3\text{N}_4$, **1**, and $1/g\text{-C}_3\text{N}_4$ heterojunction were measured using powder samples (Fig. S4†). The absorption spectra, which were converted from the reflectance data by the Kubelka–Munk function $F(R) = (1 - R)^2/2R$,³⁰ are shown in Fig. 6a. As shown in Fig. 6a, $g\text{-C}_3\text{N}_4$, **1**, and $1/g\text{-C}_3\text{N}_4$ exhibited well-defined abrupt absorption edges from which the band gap (E_g) can be estimated at 2.72 eV, 2.48 eV, and 2.58 eV, respectively. The band gap of the $1/g\text{-C}_3\text{N}_4$ heterojunction is greater than that of compound **1**, and lower than that of $g\text{-C}_3\text{N}_4$. When $g\text{-C}_3\text{N}_4$ was loaded, the absorption band gap of the $1/g\text{-C}_3\text{N}_4$ heterojunction underwent a blueshift compared to that of pure **1**. The band gap of $1/g\text{-C}_3\text{N}_4$ is smaller than that of

Fig. 6 (a) UV-vis-NIR absorption spectra of $g\text{-C}_3\text{N}_4$, **1** and $1/g\text{-C}_3\text{N}_4$. (b) Photocurrent densities of **1**, $g\text{-C}_3\text{N}_4$, and the $1/g\text{-C}_3\text{N}_4$ heterojunction under Xe light illumination at a power of 150 W.

bromoargenate hybrids containing organic cations, such as $[\text{H}_2\text{-DABCO}][\text{Ag}_2\text{Br}_4(\text{DABCO})]$ ($E_g = 3.44$ eV),³¹ and $[\text{H}_3(\text{DABCO})_2][\text{Ag}_3\text{-Br}_6]$ (DABCO = 1,4-diazabicyclo[2.2.2]octane) ($E_g = 4.20$ eV).³² However, these values are greater than those for the TM-complex containing bromoargenate hybrids $[\text{TM}(\text{phen})_3]_2\text{Ag}_{13}\text{-Br}_{17}\cdot 2\text{DMSO}\cdot 3\text{H}_2\text{O}$ (phen = 1,10-phenanthroline) [$E_g = 2.18$ eV (Fe), 2.15 eV (Co), 2.24 eV (Ni)], $[\text{Fe}(\text{phen})_3][\text{Ag}_2\text{Br}_4\cdot\text{DMF}]$ ($E_g = 2.19$ eV),^{25a} $[\text{TM}(\text{phen})_3][\text{PbAg}_2\text{Br}_6]$ [$E_g = 1.99$ eV (Fe), 2.74 eV (Ni)],³³ $[\text{NH}_4][\text{Fe}(2,2'\text{-bipy})_3]_2[\text{Ag}_6\text{Br}_{11}]$ ($E_g = 1.90$ eV),²⁶ and iodoargenate hybrids $[\text{TM}(2,2'\text{-bipy})_3][\text{Ag}_5\text{I}_7]$ [$E_g = 1.94$ eV (Co), 2.10 eV (Ni), 2.58 eV (Zn)],³⁴ and $\text{K}_x[\text{TM}(2,2'\text{-bipy})_3]_2\text{Ag}_6\text{I}_{11}$ ($x = 0.89\text{--}1$) [$E_g = 2.01$ eV (Mn), 1.66 eV (Fe), 1.75 eV (Co), 1.85 eV (Ni), 2.08 eV (Zn)].⁶

The $1/g\text{-C}_3\text{N}_4$ heterojunction was photosensitive to visible light, and exhibited rapid photocurrent response under visible light illumination at room temperature. As shown in Fig. 6b, the photocurrent density of the $1/g\text{-C}_3\text{N}_4$ heterojunction increased dramatically once the light was turned on, and immediately decreased to approximately zero when the light was turned off. After illumination by Xe light at a power of 150 W, the photocurrent density of the $1/g\text{-C}_3\text{N}_4$ heterojunction was $24.58 \mu\text{A cm}^{-2}$ in the first on/off switch, and stabilized at $23.68 \mu\text{A cm}^{-2}$ after nine on/off switch cycles, indicating that the $1/g\text{-C}_3\text{N}_4$ heterojunction had a good reproducible photocurrent response. The $1/g\text{-C}_3\text{N}_4$ heterojunction exhibited much stronger photocurrent response than the pure compound **1** and $g\text{-C}_3\text{N}_4$. The pure compound **1** and $g\text{-C}_3\text{N}_4$ had steady photocurrent densities of $8.92 \mu\text{A cm}^{-2}$ and $2.94 \mu\text{A cm}^{-2}$, respectively, under the same visible light illumination. The current density of $1/g\text{-C}_3\text{N}_4$ is 2.65 and 8.05 times higher than those of pure **1** and $g\text{-C}_3\text{N}_4$, respectively. The enhanced photocurrent response suggested more effective separation of photogenerated carriers in the $1/g\text{-C}_3\text{N}_4$ heterojunction when it was illuminated by visible light. The doping of 2-D semiconducting material of $g\text{-C}_3\text{N}_4$ can promote the charge separation, and inhibit the recombination of photoexcited electrons and holes, therefore the photocurrent intensity is enhanced.^{14,35} The stability of the photocurrent response of the $1/g\text{-C}_3\text{N}_4$ heterojunction was investigated by repeated measurements. As shown in Fig. S5†, the current intensities of the heterojunction were 26.08 and $24.92 \mu\text{A cm}^{-2}$ in the first and second cycling measurements, respectively. The current intensity decreased slightly during the third cycle, and stabilized at $23.68 \mu\text{A cm}^{-2}$ after three cycles, indicating the excellent photocurrent reproducibility and durability of the $1/g\text{-C}_3\text{N}_4$ heterojunction.

Photocatalytic properties

In the past twenty years, the discharge of harmful organic pollutants from industries has led to increasing water pollution. Photocatalysis is an environmentally friendly and economical sewage treatment method, that uses photogenerated electrons and holes on the surface of the catalyst to oxidize organic pollutants into nontoxic small molecules.³⁶ The photocatalytic behaviors of compound **1** and $1/g\text{-C}_3\text{N}_4$ heterojunction were evaluated by the model reaction of crystal violet (CV) photodegradation in aqueous solution under visible light

irradiation. The change in the CV concentration was monitored by the intensity of the absorption maximum at a wavelength of 583 nm (Fig. S6†). The degradation efficiency was expressed as C_t/C_0 , where C_0 and C_t are the initial and instantaneous concentrations of the dye, respectively. After the mixture of CV and the catalyst was stirred in the dark for 30 min, the adsorption between the catalyst and dye reached equilibrium, and approximately 10.6%, 6.0% and 7.6% of the dye was adsorbed on the $g\text{-C}_3\text{N}_4$, **1** and $1/g\text{-C}_3\text{N}_4$ heterojunction, respectively (Fig. S7†). The blank experiment showed that approximately 7.7% of CV was degraded in the absence of catalyst after light irradiation for 60 min. The degradation conversions of CV over $g\text{-C}_3\text{N}_4$ and **1** were 33.0% and 54.1%, respectively, after light irradiation for 60 min. The $1/g\text{-C}_3\text{N}_4$ heterojunction exhibited much more photocatalytic activity than $g\text{-C}_3\text{N}_4$ and compound **1**. In the presence of $1/g\text{-C}_3\text{N}_4$ heterojunction, the CV solution became almost colorless after 60 min of illumination, and the degradation conversion of CV reached 98.0% (Fig. 7a). The $1/g\text{-C}_3\text{N}_4$ heterojunction exhibited the highest degradation efficiency, which was in accordance with it having the strongest photocurrent response. The high photocurrent density implied efficient separation of photogenerated carriers,³⁷ and therefore, the photocatalytic activity was improved. As shown in Fig. 7b, the plot of $\ln(C_0/C_t)$ against the irradiation time t fits the formula $\ln(C_0/C_t) = kt$, indicating that the photodegradation reactions catalyzed by $g\text{-C}_3\text{N}_4$, compound **1** and $1/g\text{-C}_3\text{N}_4$ heterojunction conform to first-order kinetics. The kinetic rate constants k of the degradation reactions are 0.0774, 0.0118, and 0.0519 min^{-1} for $g\text{-C}_3\text{N}_4$, **1** and $1/g\text{-C}_3\text{N}_4$, respectively. The $1/g\text{-C}_3\text{N}_4$ heterojunction

had the highest rate constant, which was 6.7 and 4.4 times greater than that of pure $g\text{-C}_3\text{N}_4$ and compound **1**, indicating the synergistic effect between **1** and $g\text{-C}_3\text{N}_4$ towards visible-light-driven photocatalytic performance in the degradation of CV. The $1/g\text{-C}_3\text{N}_4$ exhibited distinctly higher photocatalytic activity for CV degradation in comparison with the TM(II)-complex containing haloargentate hybrids [TM(phen)₃]₂Ag₁₃Br₁₇·2DMSO·3H₂O (TM = Fe, Co, Ni), [Cu(phen)₂(Br)]AgBr₂,^{25a} [Ni(2,2'-bipy)₃][H-2,2'-bipy]Ag₃I₆,⁶ [Zn(2,2'-bipy)₃]Ag₃I₅,^{11b} [Mn(2,2'-bipy)₂(DMF)₂]Ag₅I₇, and [Zn(DMF)₂(H₂O)₂](4,4'-bipy)_{1.5}]Ag₅I₇·2DMF.³⁸ The degradation ratios of CV on these haloargentate hybrid catalysts were in the range of 38–71% after light irradiation for 60 min. The $1/g\text{-C}_3\text{N}_4$ heterojunction also showed higher photocatalytic activity than did the MOF/ $g\text{-C}_3\text{N}_4$ composites of NH₂-MIL-88B(Fe)/ $g\text{-C}_3\text{N}_4$ (NH₂-MIL = 2-aminoterephthalic acid), and Ce-BTC/ $g\text{-C}_3\text{N}_4$ (H₃BTC = 1,3,5-benzenetricarboxylic acid) in degradation of organic dyes.³⁹ Approximately 58% and 73% of MB dye were degraded on the two MOF/ $g\text{-C}_3\text{N}_4$ composites, respectively, after light irradiation for 60 min.

After the photocatalytic reaction, the catalyst samples of compound **1** and the $1/g\text{-C}_3\text{N}_4$ heterojunction were collected by centrifugation for powder X-ray diffraction measurements. The PXRD patterns of the catalysts were basically the same as those of the as-prepared sample, with the position of the diffraction peaks unchanged (Fig. S8†), indicating that the catalyst samples had good structural stability during photodegradation. The photocatalytic stability and durability of the photocatalyst are important aspects of its practical application. The catalytic stability of the $1/g\text{-C}_3\text{N}_4$ heterojunction was investigated by repeated experiments. As shown in Fig. 8a, the $1/g\text{-C}_3\text{N}_4$ heterojunction exhibited relatively steady photocatalytic activities in five consecutive cycles. The photocatalytic ratio remains at 93% after five catalytic cycles in the degradation of CV.

Possible photodegradation mechanism

It is generally believed that photoinduced superoxide ($\cdot\text{O}_2^-$) and hydroxyl radicals ($\cdot\text{OH}$), and positive holes (h^+) are active substances for the photocatalytic degradation of organic pollutants in aqueous solution. Benzoquinone (BQ), *tert*-butanol (TBA), and ammonium oxalate (AO) which are quenchers of $\cdot\text{O}_2^-$ and $\cdot\text{OH}$ radicals, and h^+ holes, respectively, were added to the photocatalytic reaction to explore the reactive species during the photodegradation of CV catalyzed by the $1/g\text{-C}_3\text{N}_4$ heterojunction. As shown in Fig. 8b and S9† all the degradation ratios of CV over the $1/g\text{-C}_3\text{N}_4$ heterojunction decreased when BQ, AO and TBA were added to the catalytic reaction. The degradation ratios decreased from 98.0% without quenchers to 29.2%, 25.1%, and 46.9% in the presence of BQ, AO and TBA, respectively, after light irradiation for 60 min (Fig. 8b), indicating that all h^+ , $\cdot\text{O}_2^-$, and $\cdot\text{OH}$ radicals are the reactive species during the degradation on the $1/g\text{-C}_3\text{N}_4$ heterojunction.

The oxidation ability of photogenerated holes of photocatalysts can be determined by the energy of the

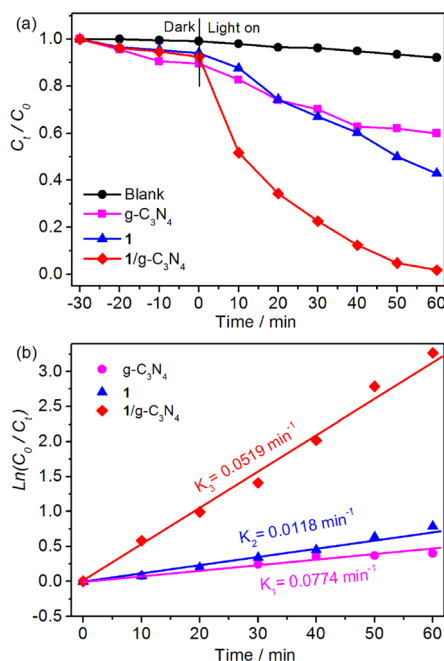

Fig. 7 (a) Photocatalytic activities in CV degradation over $g\text{-C}_3\text{N}_4$, **1**, and $1/g\text{-C}_3\text{N}_4$ heterojunction. (b) Linear relationship of $\ln(C_0/C_t)$ versus reaction time t over $g\text{-C}_3\text{N}_4$, **1**, and $1/g\text{-C}_3\text{N}_4$ heterojunction during the photodegradation of CV.

valence band.⁴⁰ The potentials of the valence band (E_{VB}) and conduction band (E_{CB}) of g-C₃N₄ are 1.50 eV and -1.22 eV, respectively.⁴¹ The VB XPS spectrum showed that the valence band edge of **1** is located at 1.03 eV (Fig. S10[†]), and therefore the conduction band edge of **1** is located at -1.45 eV. The 1/g-C₃N₄ hybrid is a typical type II heterojunction based on the potentials of the valence and conduction bands of g-C₃N₄ and **1** (Fig. 9).^{14c,42} When the 1/g-C₃N₄ heterojunction is irradiated by visible light, photogenerated electrons are generated in the conduction band (CB) and positive holes (h^+) remain in the valence band (VB) (eqn (1)).⁴³ The photogenerated electrons on the CB of **1** can jump to the less negative CB of g-C₃N₄, while the h^+ holes in the VB of g-C₃N₄ move to the VB of **1** in the 1/g-C₃N₄ heterojunction (eqn (2), (3) and Fig. 9). The doping of g-C₃N₄ on **1** can effectively promote the charge separation, and minimize the recombination of the electron-hole pairs. The holes on the VB of **1** could react with water to produce extremely reactive hydroxyl radicals ($\cdot\text{OH}$) as shown in eqn (4), or directly participate in the oxidization of the organic dye, whereas the electrons on the CB of g-C₃N₄ could combine with oxygen to form the superoxide radical $\cdot\text{O}_2^-$ according to eqn (5).⁴³ The formation of a type II heterojunction by doping g-C₃N₄ leads to the migration of charge carriers in the opposite direction.^{14c,44} This significantly enhances the electron-hole spatial separation on various parts of the heterojunction to prevent the charge recombination, and to prolong the lifetime of free electrons and holes, which is helpful for the generation of reactive species h^+ , $\cdot\text{OH}$ and $\cdot\text{O}_2^-$ on the surface of the heterojunction. The synergistic effect of the three h^+ , $\cdot\text{O}_2^-$, and $\cdot\text{OH}$ reactive species accounts for the much higher

Fig. 9 Schematic diagram illustrating the photocatalytic mechanism for CV degradation over the 1/g-C₃N₄ heterojunction under visible light irradiation.

degradation rate of the 1/g-C₃N₄ heterojunction than that of pure **1** and g-C₃N₄ during the photodegradation of CV.

Conclusions

In summary, a 2-D bromoargentate hybrid $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ (**1**) was prepared in a C₂H₅OH/DMF mixed solvent under solvothermal conditions. The $[\{\text{Cu}(\text{phen})\}_2(\mu\text{-OH})_2(\text{Ag}_3\text{Br}_5)]_n$ layers were successfully loaded on the surface of g-C₃N₄ heterojunction by *in situ* growth under the same solvothermal conditions, and 1/g-C₃N₄ heterojunction was obtained. The 1/g-C₃N₄ heterojunction performed a stable and reproducible photocurrent response. Its photocurrent density is 2.65 and 8.05 times higher than those of parent **1** and g-C₃N₄, respectively, indicating that the formation of heterojunction is helpful for the separation of photogenerated carriers, therefore, the photocurrent intensity is enhanced. The improved photocatalytic efficiency of the 1/g-C₃N₄ heterojunction compared to that of parent **1** and g-C₃N₄ demonstrated the excellent synergistic effect of the 1/g-C₃N₄ heterojunction cocatalyst on CV degradation. This result showed that new efficient visible-light photocatalysts can be obtained by the rational design and construction of g-C₃N₄-based heterogeneous heterojunctions with the aim of promising applications in the area of solar energy conversion and environmental remediation.

Experimental section

Materials and methods

The g-C₃N₄ sample was prepared by thermal polymerization using urea as the precursor according to a previously reported

method.⁴⁵ 1.5 g of urea was ground evenly placed in a ceramic crucible, heated to 550 °C at a heating rate of 5 °C min⁻¹ in a muffle furnace and kept at 550 °C for 4 h. A faint yellow product of g-C₃N₄ was obtained after cooling to room temperature. All other chemicals (Cu(NO₃)₂·3H₂O, AgBr, KBr, phen, *tert*-butyl alcohol (TBA), 1,4-benzoquinone (BQ), ammonium oxalate (AO), crystal violet (CV), C₂H₅OH, and DMF) were purchased from McLean Chemical Reagents Co., Ltd. (Shanghai, China). All of the chemicals used in the experiments were of analytical grade and used without any further purification. Physical and chemical measurements and characterizations, including elemental analysis, FT-IR, powder X-ray diffraction (PXRD), scanning electron microscopy (SEM), X-ray energy dispersive spectroscopy (EDS), X-ray photoelectron spectroscopy (XPS), solid-state UV-vis reflectance spectroscopy, photocurrent response measurements, and photocatalytic tests, are provided in the ESI.†

Syntheses

Synthesis of [Cu(phen)]₂(μ-OH)₂(Ag₃Br₅)_n (1). Cu(NO₃)₂·3H₂O (242 mg, 1.0 mmol), AgBr (282 mg, 1.5 mmol), KBr (298 mg, 2.5 mmol) and phen (270 mg, 1.5 mmol) were mixed in 4 ml of C₂H₅OH and 2 ml of DMF under stirring. After being ultrasonically dispersed for 10 min, the mixture was transferred to a polytetrafluoroethylene (PTFE)-lined stainless steel autoclave with a volume of 15 mL. The sealed autoclave was heated at 110 °C for 5 days, and then naturally cooled to room temperature. The blue block crystals were collected by filtration, washed with ethanol, and stored under vacuum (yield: 448 mg, 72% based on AgBr). Anal. calcd. for C₂₄H₁₈N₄O₂Cu₂Ag₃Br₅ (1): C, 23.16; H, 1.46; N, 4.50. Found: C, 22.91; H, 1.39; N, 4.39%. IR (KBr, cm⁻¹): 3578 (br, m), 3447 (m), 3068 (m), 2949 (m), 2881 (m), 1608 (m), 1576 (m), 1523 (w), 1439 (s), 1376 (s), 1291 (m), 1173 (w), 1088 (w), 978 (w), 909 (w), 828 (w), 759 (s), 647 (m).

Synthesis of the 1/g-C₃N₄ heterojunction. g-C₃N₄ (46 mg), Cu(NO₃)₂·3H₂O (121 mg, 0.50 mmol), AgBr (141 mg, 0.75 mmol), KBr (149 mg, 1.25 mmol) and phen (135 mg, 1.25 mmol) were mixed in 2 ml of C₂H₅OH and 1 ml of DMF under stirring. After being ultrasonically dispersed for 30 min, the mixture was transferred to a PTFE-lined stainless steel autoclave with a volume of 15 mL. The sealed autoclave was heated at 110 °C for 3 days. After cooling to room temperature, powder product was washed with ethanol and 1/g-C₃N₄ heterojunction was obtained. IR (KBr, cm⁻¹): 3433 (br, m), 3070 (m), 2920 (w), 2881 (w), 1626 (m), 1574 (m), 1525 (s), 1457 (m), 1435 (m), 1395 (s), 1314 (s), 1233 (s), 1202 (s), 1086 (m), 1000 (w), 889 (w), 805 (m), 759 (s), 647 (m).

X-ray crystal structure determination

The data of compound **1** were collected on a Bruker CCD diffractometer using graphite-monochromated Mo-K α radiation with an ω -scan method to a maximum 2θ value of 50.70°. An empirical absorption correction was conducted for all the crystals by using the multi-scan method. The structure was solved by SHELXS-14.^{46a} and refinement was performed

against F^2 using SHELXL-14.^{46b} All the nonhydrogen atoms were refined anisotropically. The hydrogen atoms were positioned with an idealized geometry and refined using the riding model. The technical details of the data acquisition and selected refinement results are summarized in Table S1.†

Data availability statement

All relevant data are within the manuscript and its ESI.†
