# Two-gap topological superconductor LaB<sub>2</sub> with high $T_c = 30$ K†

Chin-Hsuan Chen,<sup>‡a</sup> Ye-Shun Lan,<sup>‡a</sup> Angus Huang<sup>a</sup> and Horng-Tay Jeng<sup>id</sup>\*<sup>abc</sup>

Since two gap superconductivity was discovered in MgB<sub>2</sub>, research on multigap superconductors has attracted increasing attention because of its intriguing fundamental physics. In MgB<sub>2</sub>, the Mg atom donates two electrons to the borophene layer, resulting in a stronger gap from the  $\sigma$  band and a weaker gap from the  $\pi$  bond. First-principles calculations demonstrate that the two gap anisotropic superconductivity strongly enhances the transition temperature of MgB<sub>2</sub> in comparison with that given by the isotropic model. In this work, we report a three-band (B- $\sigma$ , B- $\pi$ , and La-d) two-gap superconductor LaB<sub>2</sub> with very high  $T_c = 30$  K by solving the fully anisotropic Migdal–Eliashberg equation. Because of the  $\sigma$  and  $\pi$ -d hybridization on the Fermi surface, the electron–phonon coupling constant  $\lambda = 1.5$  is significantly larger than the  $\lambda = 0.7$  of MgB<sub>2</sub>. Our work paves a new route to enhance the electron–phonon coupling strength of multigap superconductors with d orbitals. On the other hand, our  $\mathbb{Z}_2$  analysis reveals that LaB<sub>2</sub> belongs to the weak topological semimetal category, leading to a possible topological superconductor with the highest  $T_c$  to date. Moreover, upon applying pressure and/or doping, the topology is tunable between weak and strong with  $T_c$  varying from 15 to 30 K, opening up a flexible platform for manipulating topological superconductors.

## Introduction

Superconductivity is one of the most important and mysterious research fields not only because of the intriguing fundamental physics behind it but also because of its high potential for future industry. Yet the critical temperature  $T_c$  of superconductors is generally too low for practical applications. Thus enhancing the  $T_c$  of superconductors is an essential issue in condensed matter

### New concepts

To date, available topological superconductors such as PbTaSe<sub>2</sub>, PdBi, RhPb<sub>2</sub>, as well as WS<sub>2</sub> and SnPbTe/Pb heterostructures all belong to S-wave single-gap BCS superconductors. In our work, we present a two-gap topological superconductor LaB<sub>2</sub>, which is a totally new concept to this field. Therefore, the impact to the topological superconductor, Majorana fermion, and quantum computing research fields will be strong. So far, available candidates such as PbTaSe<sub>2</sub>, PdBi, RhPb<sub>2</sub>, as well as WS<sub>2</sub> and SnPbTe/Pb heterostructures published in high-impact journals in recent years all have  $T_c$  below 10 K. Such a low  $T_c$  causes tremendous difficulties for accurately measuring the possible Majorana fermions experimentally. Thus, it is of great importance to discover high- $T_c$  topological superconductors. In this work, we report a record-breaking high  $T_c$  of 30 K in the topological superconductor LaB<sub>2</sub>, comparing highly favorably over all the available candidates.

physics. One successful approach to raise  $T_c$  is by applying pressure. In recent years, nearly room temperature  $T_c$  have been found in hydrogen-rich hydrides under high pressure such as H<sub>3</sub>S,<sup>1</sup> LaH<sub>10</sub>,<sup>2</sup> and NaH<sub>6</sub>.<sup>3,4</sup> The other approach to enhance the  $T_c$  of superconductors is through the anisotropic pairing or multigap mechanism such as in conventional superconductor magnesium diboride MgB<sub>2</sub>.<sup>5,6</sup> In particular, the anisotropic pairing of unconventional superconductors, with the Cooper pairing different from the conventional s-wave pairing, has attracted extensive attention because of the many-body interactions among d-electrons in cuprate<sup>7–10</sup> and iron-based superconductors.<sup>11,12</sup> On the other hand, topological superconductors with p-wave pairing have also been predicted in Sr<sub>2</sub>RuO<sub>4</sub>.<sup>13</sup>

MgB<sub>2</sub>, known as a classic example of an anisotropic pairing superconductor, has shown great promise for enhancing  $T_c$  through two-gap phonon-mediated superconductivity. The Fermi surfaces (FSs) of MgB<sub>2</sub> comprise  $\sigma$  bonds ( $s + p_{xy}$  orbitals of B atoms) and  $\pi$  bonds ( $p_z$  orbitals of B atoms).<sup>5,14–19</sup> The two separated FSs in reciprocal space lead to two superconducting (SC) gaps  $\Delta_\sigma \approx 7$  meV and  $\Delta_\pi \approx 2$ –3 meV at 0 K<sup>20–23</sup> with the gaps closed at the transition temperature  $T_c = 39$  K.<sup>20–23</sup> Theoretical investigations demonstrate that the anisotropic effect increases the superconducting temperature of MgB<sub>2</sub> from

‡ These authors contributed equally to this work.

19 K to 55 K in the harmonic approximation. Additionally, the anharmonicity increases the phonon energy of the  $E_{2g}$  mode at the Gamma point from 62.7 meV to 75.9 meV and decreases the total EPC strength from  $\lambda = 0.73$  to  $\lambda = 0.61$ . Consequently,  $T_c$  decreases from 55 K to 39 K,<sup>6</sup> being in good consistence with the experimental  $T_c$ . The two-gap behavior exhibits exotic properties such as giant-paramagnetic response,<sup>24</sup> skyrmionic states,<sup>25,26</sup> hidden criticality,<sup>27,28</sup> and time-reversal symmetry breaking.<sup>29,30</sup>

In addition to bulk  $MgB_2$ , several systems have been proposed to exhibit multigap superconductivity. For example, two to three SC gaps with the transition-temperatures  $T_c = 20$  K, 70 K, and 34.5 K were reported in monolayer of  $MgB_2$ ,  $CaB_2$ , and  $ScB_2$ .<sup>31,32</sup> The trilayers of  $CaB_4$ ,  $GaB_4$ ,  $BeB_4$  and  $LiB_4$  films have multigaps with  $T_c$  of 64 K, 51 K, 39 K and 32 K, respectively.<sup>32,33</sup> Four SC gaps with a  $T_c = 52$  K were predicted in trilayer system  $MgB_4$  above bulk  $MgB_2$ .<sup>33</sup> Other than the magnesium boride family, multiband superconductivity has also been predicted in the hole doped  $LiBC$  with  $T_c = 100$  K,<sup>34</sup> bulk  $AlB_2$  with  $T_c = 9$  K,<sup>16,35</sup> and thin film  $AlB_2$  with  $T_c = 17$ –26.5 K.<sup>16,35</sup> These predictions show that the honeycomb layer structure with  $sp_2$  hybridized orbitals is essential for finding multigap superconductivity. To date, bulk  $MgB_2$  has been confirmed as a two-gap superconductor,<sup>36</sup> while the other predicted multigap phonon-mediated systems are yet to be confirmed in future experiments.

In this work, we investigate the superconductivity in the  $LaB_2$  compound in the same crystal structure as  $MgB_2$  through first-principles calculations. The superconducting critical temperature  $T_c^{McMillan} = 22$  K is obtained for  $LaB_2$  via the Allen–Dynes modified McMillan formula, while two-gap superconductivity with a notably higher  $T_c^{aniso} = 30$  K is obtained through solving the fully anisotropic Migdal–Eliashberg equations. In addition, our  $\mathbb{Z}_2$  analysis reveals  $LaB_2$  to be a weak topological superconductor with the highest  $T_c$  in comparison with available candidates. The topology is tunable between weak and strong with superconducting  $T_c$  varying from 15 to 30 K upon applying pressure and/or doping, serving as a flexible candidate for topological superconductors.

## Results and discussion

It is well known that magnesium diboride  $MgB_2$  exhibits two-gap superconductivity with the highest ambient-pressure  $T_c$  to date. By substituting the magnesium atom with transition-metal elements, we systematically investigated the superconductivity of the transition-metal diboride  $XB_2$ . Among them, we found that  $LaB_2$  can be stabilized in the same crystal structure as  $MgB_2$  under ambient pressure, while it also shows two-gap superconductivity with a fairly high  $T_c$  of 30 K.  $LaB_2$  is composed of alternate honeycomb boron and metallic lanthanum layers. The crystal structure with space group  $P6/mmm$  is shown in Fig. 1(a) and (b). The optimized lattice parameters  $a = 3.32$  Å and  $c/a = 1.30$  are obtained from geometry relaxation calculations based on density functional theory (DFT).

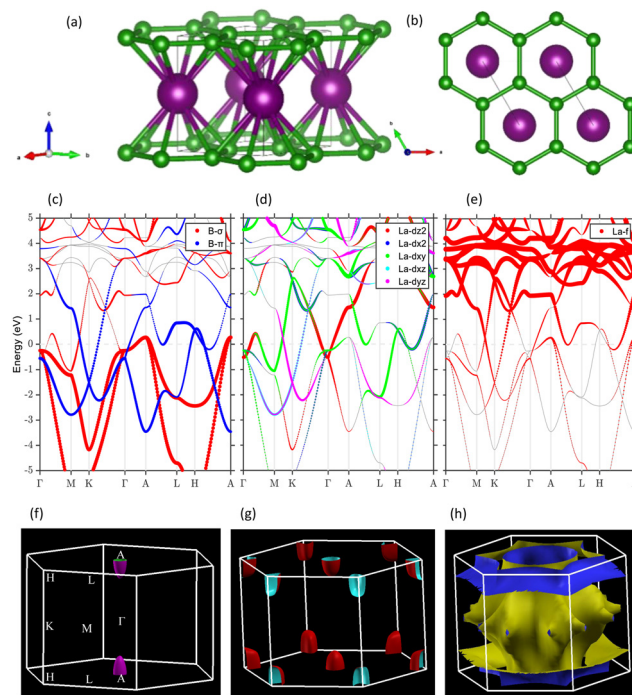

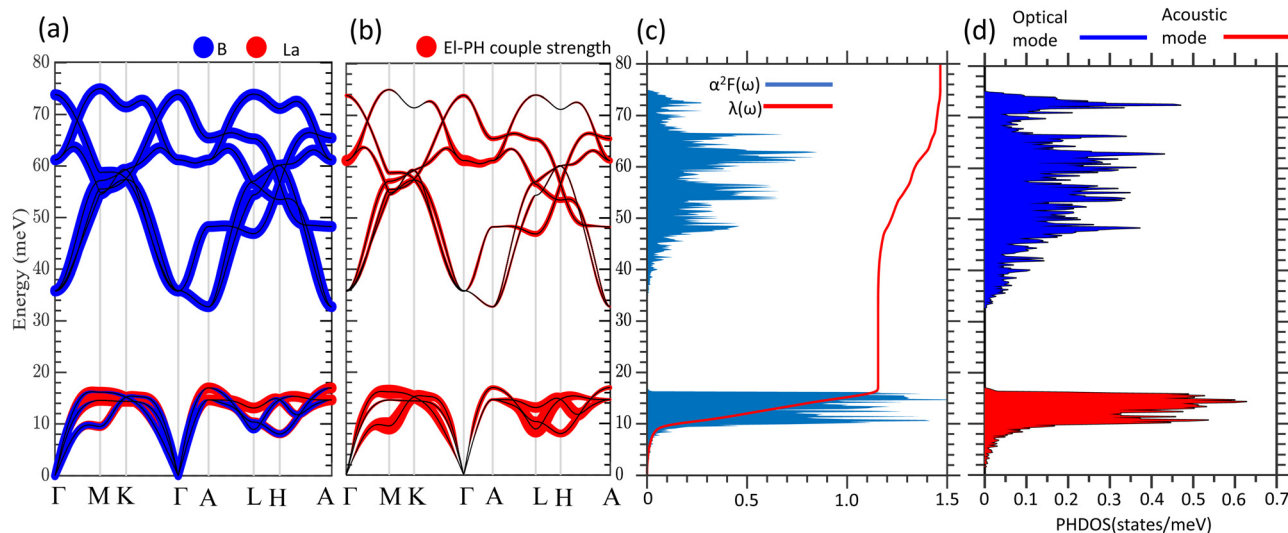

Fig. 1  $LaB_2$  hexagonal crystal structure and electronic properties. (a) Side view and (b) top view of the  $LaB_2$  lattice structure. (c)–(e) Electronic band structure of  $LaB_2$  projected onto the B- $\sigma$  and B- $\pi$ , La-d, and La-f orbital, respectively. The size of the colored spheres indicates the contributions from the atomic orbitals. (f)–(g) The Fermi surface near the H and A points is dominated by the boron  $\pi$  bond and boron  $\sigma$  bond, respectively. (h) The Fermi surface is dominated by the lanthanum d bond.

The atom-orbital-decomposed band structures depicted in Fig. 1(c)–(e) show the detailed characters of each electronic band. Near the Fermi level ( $E_F$ ), the doubly degenerate boron- $\sigma$  bands cross  $E_F$  from  $\Gamma$  to A, forming a small hole pocket around A (Fig. 1(c)). Similar to  $MgB_2$ , this slowly rising flat B- $\sigma$  ( $sp^2$ ) band along  $\Gamma$ –A reflects weak interlayer interactions in  $LaB_2$  with a slightly higher  $E_F$  due to the relatively higher ionicity of La. One boron- $\pi$  ( $p_z$ ) band also crosses  $E_F$  and forms a hole pocket around H (Fig. 1(c)). On the other hand, the contributions of lanthanum (La) to the electronic bands plotted in Fig. 1(d and e) demonstrate that three La-d orbitals:  $d_{z^2}$ ,  $d_{x^2-y^2}$ , and  $d_{xy}$  contribute notably to the bands near the  $\Gamma$ - and H-points, and along the H–A paths around  $E_F$ . Particularly, the La  $d_{xy}$  orbital takes part in the B- $\pi$  hole pocket around H, while most of the La-f bands move from 2 to 5 eV above the Fermi level (Fig. 1(e)) with nontrivial hybridizations with the B- $\sigma$  hole pocket around A near  $E_F$ .

The above mentioned electronic bands form three Fermi surfaces as illustrated in Fig. 1(f)–(h). They are respectively the small hole pockets around A constructed mainly by the B- $\sigma$  orbital with partially the La-f orbital, the paraboloid hole pockets around H mostly comprised by the B- $\pi$  with some La  $d_{xy}$ , and the star-shaped cylinder Fermi surface surrounding  $\Gamma$  composed of the La d orbitals. With the above band character analysis, we have adopted the  $sp^2$ ,  $p_z$  orbital of B atoms and  $d_{z^2}$ ,  $d_{x^2-y^2}$ ,  $d_{xy}$ , f orbital of La atoms as the Wannier basis to build the tight-binding Hamiltonian and generate the Wannier band

structure using Wannier90 code. This Wannier basis set can well reproduce the DFT band structures from  $-10$  eV to  $2$  eV with high quality, and is used for the topological analysis as will be discussed later.

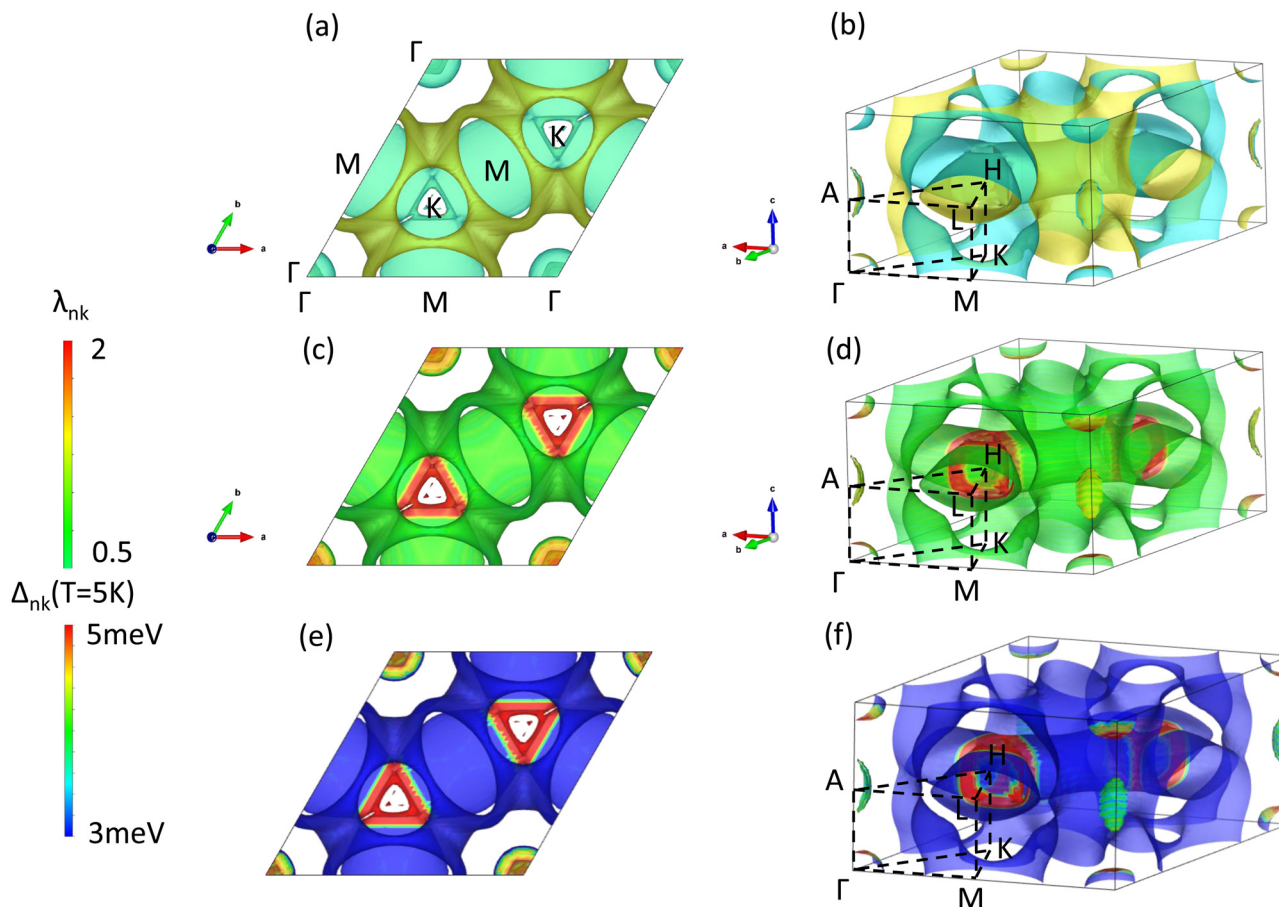

The superconductivity of LaB<sub>2</sub> is explored through the phonon dispersion and electron–phonon coupling (EPC) calculations based on density function perturbation theory (DFPT). Fig. 2(a) shows the phonon band structures with the atomic contributions resolved. The acoustic phonon modes in the low frequency region less than  $16$  meV are mainly derived from the vibrations of heavy La atoms coupled with light B atoms, while the light B atoms oscillate quickly and dominate the high frequency region above  $32$  meV. In between, there is a notable phonon band gap, indicating a low scattering rate between acoustic and optical phonons. The phonon density of states (DOSs) depicted in Fig. 2(d) shows the overall narrow bandwidth with high intensity for acoustic phonon bands, and wide bandwidth with low intensity for optical phonon bands. Fig. 2(b) shows the phonon-dependent EPC strength  $\lambda_{qv}$  of LaB<sub>2</sub>. For the acoustic branches, there exist three Kohn anomalies around the  $M$ ,  $L$ , and  $H$  points with the phonon energy significantly lowered to  $\sim 10$  meV. These three Kohn anomalies are associated with strong EPC strengths up to  $\lambda_M = 1.68$ ,  $\lambda_L = 2.01$ , and  $\lambda_H = 0.6$ , respectively. For the optical branches, the phonon modes (point group  $E_{2g}$ ) with significant EPC locate at  $\sim 60$  meV from  $\Gamma$ - to  $A$ -point. The maximum EPC strength  $\lambda_q = 0.46$  here is much smaller than that of the Kohn anomalies in the acoustic branches. The Eliashberg spectral function presented in Fig. 2(c) demonstrates a strong peak from  $10$  to  $16$  meV with the Kohn anomalies dominating the lower part and with the relatively flat phonon bands dominating the higher part of the acoustic phonon bands. This strong acoustic phonon Eliashberg spectral function is closely related to the heavy atom La as can be seen from the atom-resolved phonon band structure in Fig. 2(a). As for the optical phonon modes,

the Eliashberg spectral function is generally smaller than the acoustic counterparts. The integrated Eliashberg function over the low-frequency acoustic modes  $\lambda_A(\omega) = 1.15$  (Fig. 2(c)) is relatively strong because the Eliashberg spectral function is divided by the phonon frequency in the integral of eqn (5). Owing to the same reason, the integrated Eliashberg function over the high-frequency optical modes  $\lambda_O(\omega) = 0.32$  is lower than the acoustic counterpart, despite the wider bandwidth. Furthermore, the total EPC strength  $\lambda = 1.47$  is calculated by integrating the Eliashberg spectral function over all phonon modes, in which the acoustic phonons contribute nearly  $80\%$  of the total  $\lambda$ .

To explore possible anisotropy and multigap superconductivity in LaB<sub>2</sub>, we further solve the anisotropic Migdal–Eliashberg equations and analyze the contributions and anisotropic properties of EPC strength  $\lambda_{nk}$  for the electronic states forming the Fermi surfaces as depicted in Fig. 3. Because it has the same crystal structure as MgB<sub>2</sub>, the Fermi surface (FS) of LaB<sub>2</sub> is similar to that of MgB<sub>2</sub> as can be seen in Fig. 3(a and b). The pipe-like FS forms a honeycomb-shape 2-dimensional network over the  $k_x$ – $k_y$  plane with small Fermi pockets located within the honeycomb holes. Fig. 3(c and d) show that the strongest EPC (red) is distributed around the hexagon corners of the honeycomb network at the  $H$ -point. While the second strongest EPC (yellow and orange) distributes over the small Fermi pockets around the  $\Gamma$ - and  $A$ -points. The other regions over FS (green) show weak EPC strength only. These EPC maps demonstrate two distinct EPC features: the strongest red and the 2nd strongest yellow/orange regions depending on the  $k$ -points and the comprised atomic orbitals, evidencing the multigap superconductivity in LaB<sub>2</sub>.

The corresponding EPC-induced superconducting gaps in the Fermi surfaces over the  $BZ$  are presented in Fig. 3(e and f). Good correspondence with the EPC maps in Fig. 3(c and d) can be clearly seen, showing that the electronic states on the Fermi

**Fig. 3** EPC distribution on Fermi surface and contributions to superconducting gaps of  $\text{LaB}_2$ . (a) Top and (b) side view of the Fermi surface (FS) in the primitive BZ. Dash lines in (b) show the high symmetry lines in BZ. (c) Top and (d) side view of the momentum-resolved EPC at FS. The red color region around  $k_z = 0.4$  KH indicates the maxima EPC region. (e) Top and (f) side view of the momentum-resolved superconductivity gap at  $T = 5$  K. The red color region around  $k_z = 0.4$  KH indicates the maximum SC gap region.

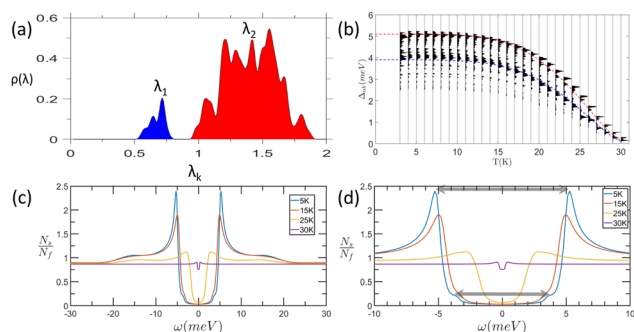

surface with higher EPC contribute strongly to the superconducting gaps. Overall, one can see two main features in the superconducting gap distributions: (I) the large gap ( $\Delta_{nk} \approx 5$  meV)

regions around the zone center and  $H$ -point at  $k_z \approx 0.4$  indicated by red color; (II) the middle gap ( $\Delta_{nk} \approx 4$  meV) areas denoted by yellow and orange colors around  $\Gamma$  and  $A$  points. Combining these two main features in the superconducting-gap maps (Fig. 3(e and f)) with the strongest and second strongest EPC distributions (Fig. 3(c and d)), we demonstrate clearly the two-gap superconductivity in  $\text{LaB}_2$  similar to  $\text{MgB}_2$ .

To quantify the EPC distribution over the BZ presented in Fig. 3(c and d), the EPC distribution  $\rho_{nk}$  as a function of the EPC strength  $\lambda_{nk}$  is integrated through

$$\rho(\lambda) = \sum_n \int_{\Omega_{\text{BZ}}} \frac{d^3k}{\Omega_{\text{BZ}}} \delta(\lambda - \lambda_{nk}) \delta(\epsilon_{nk} - E_F), \quad (1)$$

and is depicted in Fig. 4(a). It can be seen clearly that there exist two distinct peaks at  $\lambda_1 \sim 0.75$  and  $\lambda_2 \sim 1.5$ . The former is a low-intensity peak with a narrow width while the latter is a high-intensity peak with a wide width. According to the orbital character analysis based on Fig. 1(c-e) and 3(c, d), the weak  $\lambda_1$  peak is mainly composed of the B- $\sigma$  band ( $A$ -point) as well as the B- $\pi$  and La- $d_{z^2}$  hybridized band ( $\Gamma$ -point) along the  $\Gamma$ - $A$ - $\Gamma$   $k$ -path crossing the Fermi level. These two bands (B- $\sigma$  and B- $\pi$  La- $d_{z^2}$  hybridized band) contribute equally to the EPC  $\lambda_1$  with

**Fig. 4** EPC strength distribution, superconducting gap and DOS of  $\text{LaB}_2$ . (a) EPC distribution  $\rho_{nk}$  as a function of the EPC strength  $\lambda_{nk}$ . (b) Superconductivity gap distribution at the Fermi surface from  $T = 3$  K to  $T = 30$  K. Blue and red dash curves are obtained from fitting the superconductivity gap equation using the maximum gap distribution. (c) Quasiparticle density of states at  $T = 5$  K, 15 K, 25 K, 30 K (blue, red, yellow, and purple curves, respectively). (d) Zoom in plot of (c). Gray arrows indicate the 2 gaps.

the same gap (Fig. 3(e, f) and 4(b)). This is the reason why we observe only two EPC peaks in Fig. 4(a) even though we see three bands (FSs) in Fig. 1(c–h). As for the strong  $\lambda_2$  peak, the main contribution is comprised of the B- $\pi$  band hybridizing with two La-d orbitals ( $d_{x^2-y^2}$  and  $d_{xy}$ ) (Fig. 1(c–e)) around the  $H$ -point along the  $L$ - $H$ - $A$   $k$ -path crossing the Fermi level, which shows a very strong EPC nature. Different from  $\text{MgB}_2$ , the EPC strengths of these B- $\pi$  La-d hybridized bands is much stronger than that of the B- $\sigma$  bond in  $\text{LaB}_2$ . The strongly enhanced EPC of the B- $\pi$  bond by hybridization with La-d orbitals demonstrates the potential of d-orbitals in superconductivity.

Fig. 4(b) shows the calculated superconductivity gap energy distribution *versus* temperature from 3 to 30 K. Overall, the two-gap features can be clearly seen. Close to the zero temperature limit, the two gap values are  $\sim 3.9$  and  $\sim 5.1$  meV for  $\Delta_1$  and  $\Delta_2$ , respectively. While above  $T = 20$  K, both the gap values decrease to zero. By using the BCS-like gap equation non-linear fit for the calculated superconducting gap functions, we obtain two curves for  $\Delta_1$  and  $\Delta_2$  as functions of temperature. The two gap curves converge to 0 at  $T = 30$  K. Fig. 4(c and d) shows the superconductivity density of states at  $T = 5, 15, 25, 30$  K. At  $T = 5$  K, one can clearly see the two peaks at  $\pm 3.9$  meV and  $\pm 5.1$  meV. At  $T = 30$  K, both the high and low energy SC gaps are nearly vanishing owing to the approaching superconducting transition temperature. Based on our fitting gap functions in Fig. 4(b) and superconductivity DOS in Fig. 4(c) and (d), we conclude the two-gap superconducting  $T_c = 30$  K.

Another important research area in borophene-metal systems is topological superconduction. The Dirac nodal line and topological surface state have been discovered in  $\text{MgB}_2$  owing to the spatial inversion symmetry and time-reversal symmetry (PT symmetry).<sup>37</sup>  $\text{MgB}_2$  is topologically nontrivial not only electronically, but also phononically. The phononic Weyl nodal line and phononic surface arc states have been reported in  $\text{MgB}_2$ .<sup>38</sup> In addition, with Mg being replaced by other metal atoms,  $\text{TiB}_2$  and  $\text{ZrB}_2$  have also been theoretically reported to show PT symmetry protected electronic Dirac nodal lines.<sup>39</sup> The topological surface state and Dirac nodal line in  $\text{ZrB}_2$  have further been detected by angle-resolved photoemission spectroscopy (ARPES).<sup>40</sup> On the one hand, these interesting electronic topological results are cornerstones for hosting Majorana fermions. On the other hand, the phononic topological results can support phonon-related phenomena such as electrical resistance, heat conduction, and phonon waveguides.<sup>38</sup>

To explore the topological properties in  $\text{LaB}_2$ , we performed topological calculations including the Wilson loop, topological index, inverted band structure, Greens function, and surface states. Here we demonstrate the main conclusion in the topological aspect given from the Wilson loop calculations for the topological index  $\mathbb{Z}_2$ . The other calculated results are presented in the ESI.† As can be seen in Fig. 5(a)–(d), the Berry phase of the Wannier center shows even winding numbers along  $k_x$  and  $k_y$  in  $BZ$ . On the contrary, the corresponding winding numbers are odd in both the  $k_z = 0$  and  $k_z = 0.5$  planes (see red lines and numbers in Fig. 5(e) and (f)). Consequently,  $\text{LaB}_2$  belongs to the weak topological insulator category<sup>41,42</sup> with the  $\mathbb{Z}_2$  index

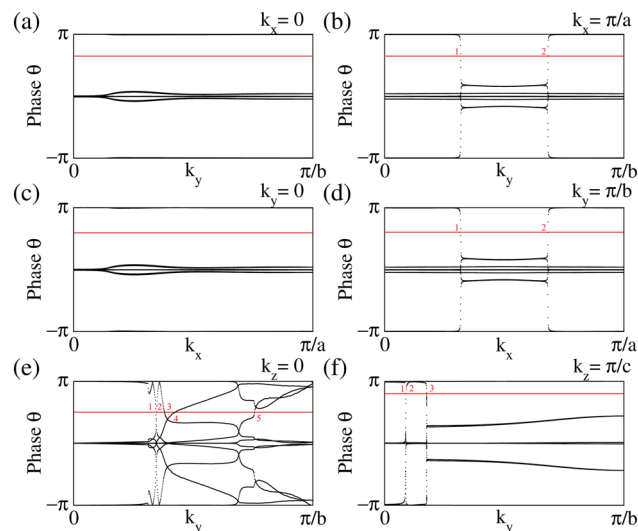

Fig. 5 Wannier charge center (WCC) evolution (Wilson loop) in three-axis planes of  $BZ$  for time-reversal invariant  $\text{LaB}_2$ . (a)  $\mathbb{Z}_2 = 0$  for  $k_x = 0.0$ . (b)  $\mathbb{Z}_2 = 0$  for  $k_x = \pi/a$ . (c)  $\mathbb{Z}_2 = 0$  for  $k_y = 0.0$ . (d)  $\mathbb{Z}_2 = 0$  for  $k_y = \pi/b$ . (e)  $\mathbb{Z}_2 = 1$  for  $k_z = 0.0$  (f)  $\mathbb{Z}_2 = 1$  for  $k_z = \pi/c$ . The solid red line is the reference line for determining the  $\mathbb{Z}_2$  topological invariance. Combining all together leads to the weak topological insulator state for  $\text{LaB}_2$ .

$\mathbb{Z}_2 = (0;001)$ . This  $\mathbb{Z}_2$  index also implies that except for the (0001) surface, the topological surface states exist in the other surfaces of  $\text{LaB}_2$ . Detailed topological surface states of  $\text{LaB}_2$  can be found in the ESI.† Moreover, this topological index could be tuned from a weak to strong topological insulator by applying strain or doping, as will be discussed later.

To date, the superconducting  $T_c$  of the available topological superconductors such as  $\text{PbTaSe}_2$ ,<sup>43,44</sup>  $\text{PdB}_i$ ,<sup>45,46</sup>  $\text{RhPb}_2$ ,<sup>47</sup> and  $\text{WS}_2$ <sup>48</sup> are all below 10 K. Such low superconducting temperatures cause tremendous difficulties for accurately measuring the possible Majorana fermions experimentally.<sup>43,49</sup> Thus our predicted high- $T_c$  of 30 K in topological superconductor  $\text{LaB}_2$  is of great importance. By applying external pressures and doping levels, we carry out the three-phase diagram calculations and present the results in Fig. 6. The superconducting temperature calculated using the Allen–Dynes modified McMillan formula varies from  $\sim 15$  K to  $\sim 30$  K, indicating  $T_c$  can be further enhanced under certain conditions. Besides, the topological behavior analyzed by the  $\mathbb{Z}_2$  topological numbers is also tunable from weak to strong topology. Both the tunable  $T_c$  and topology demonstrate that  $\text{LaB}_2$  is a rarely found convincing candidate in the topological superconductor research field.

## Conclusion

In summary, we have shown that  $\text{LaB}_2$  is a three-band two-gap topological superconductor with  $T_c^{\text{aniso}} = 30$  K by using DFPT calculations and solving the fully anisotropic Migdal–Eliashberg equations. First-principles DFPT calculations show that  $\text{LaB}_2$  is dynamically stable with  $T_c^{\text{McMillan}} = 22$  K from the Allen–Dynes modified McMillan formula. By including the anisotropic effect in the Migdal–Eliashberg equations, the  $T_c^{\text{aniso}}$  of  $\text{LaB}_2$

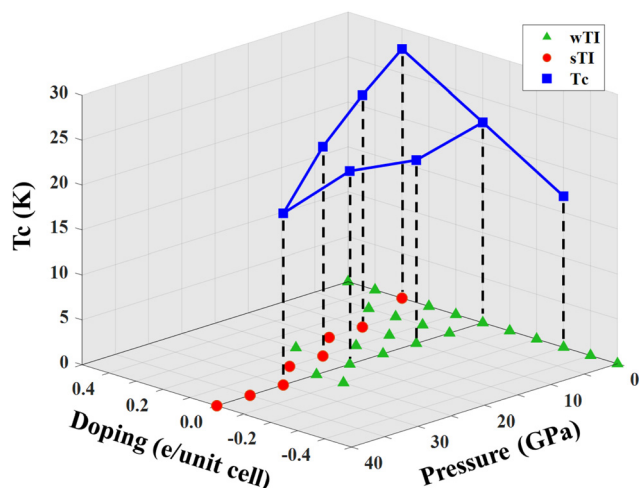

Fig. 6 Three-phase diagram of topological superconductor LaB<sub>2</sub> under various pressures and doping levels. Red dots and green triangles denote strong and weak topological insulators, respectively. Blue squares indicate the superconducting temperatures of LaB<sub>2</sub> calculated using the Allen–Dynes modified McMillan formula with the doping and pressure conditions indicated by the black dotted lines. Tunable  $T_c$  ranging from ~15 K to ~30 K and topological phases from weak to strong topological insulator are shown.

can be significantly raised up to 30 K. The calculated SC gap  $\Delta_{\sigma}(T = 0 \text{ K})$  and  $\Delta_{\pi}(T = 0 \text{ K})$  are 5.1 meV and 3.9 meV, respectively. In comparison with MgB<sub>2</sub>, the enhanced  $\lambda$  in LaB<sub>2</sub> is most likely due to the hybridization between the La-d orbitals and borophene  $\pi$  bonds. The topological index  $\mathbb{Z}_2 = (0; 001)$  indicates that LaB<sub>2</sub> belongs to the weak TI category. We suggest to adopt the d orbitals as an extra factor to enhance the electron–phonon coupling strength for multigap superconductors. Furthermore, we also show that under given pressure and doping conditions, the topology and  $T_c$  in LaB<sub>2</sub> are both tunable from weak to strong and from ~15 K to ~30 K, respectively. Our work thus paves a new platform for manipulating topological superconductors.

## Methods

Electronic property calculations are performed using the Vienna *ab initio* simulation package (VASP)<sup>50–53</sup> adopting the projector-augmented plane wave (PAW)<sup>54,55</sup> pseudopotential with the Perdew–Burke–Ernzerhof (PBE)<sup>64</sup> functional based on density functional theory (DFT). A  $k$ -mesh of  $18 \times 18 \times 18$  and kinetic energy cutoff of 400 eV are adopted in the electronic calculations. *Ab initio* phonon calculations are performed using the Quantum Espresso code<sup>56</sup> based on density functional theory (DFT). Pseudopotentials with the Perdew–Burke–Ernzerhof (PBE) exchange–correlation functional are generated by the Optimized Norm-Conserving Vanderbilt Pseudopotential (ONCVSP) code.<sup>57</sup> The plane wave basis with the cutoff kinetic energy of 80 Ry are used.  $24 \times 24 \times 24$   $k$ -mesh and  $6 \times 6 \times 6$   $q$ -mesh with Methfessel–Paxton smearing of 0.04 Ry<sup>58</sup> are adopted in the self-consistent electron and phonon calculations based on density

function perturbation theory (DFPT). Superconducting critical temperatures  $T_c$  are calculated not only by using the Allen–Dynes modified McMillan formula<sup>59</sup> in eqn (2)–(5) but also by solving the anisotropic Migdal–Eliashberg equations on the imaginary-axis<sup>20</sup> in eqn (6) and (7).

$$T_c = \frac{\omega_{\text{ln}}}{1.20} \exp\left(\frac{-1.04(1 + \lambda)}{\lambda - \mu_c^*(1 + 0.62\lambda)}\right) \quad (2)$$

The logarithmic average phonon frequency  $\omega_{\text{ln}}$  and the Eliashberg function  $\alpha^2F$  are

$$\omega_{\text{ln}} = \exp\left(\frac{2}{\lambda} \int d\omega \frac{\ln \omega}{\omega} \alpha^2 F(\omega)\right) \quad (3)$$

$$\alpha^2 F = \frac{1}{2} \int_{\text{BZ}} d\mathbf{q} \lambda_{\mathbf{q}\nu} \omega_{\mathbf{q}\nu} \delta(\omega - \omega_{\mathbf{q}\nu}) \quad (4)$$

The contribution of electron–phonon coupling from different phonon frequencies, the  $\lambda(\omega)$  is calculated through

$$\lambda(\omega) = \int_0^\omega \sum_{\mathbf{q}\nu} \lambda_{\mathbf{q}\nu}(\omega') d\omega' = \int \frac{2\alpha^2 F}{\omega'} d\omega' \quad (5)$$

$$Z_{nk}(i\omega_j) = 1 + \frac{\pi T}{\omega_j N_F} \sum_{m'j'} \int \frac{d^3 q}{\Omega_{\text{BZ}}} \frac{\omega_{j'}}{\sqrt{\omega_{j'}^2 + \Delta_{mk+q}^2(i\omega_{j'})}} \times \lambda_{nk,mk+q}(\omega_j - \omega_{j'}) \delta(\epsilon_{nk}) \quad (6)$$

$$Z_{nk}(i\omega_j) \Delta_{nk}(i\omega_j) = \frac{\pi T}{N_F} \sum_{m'j'} \int \frac{d^3 q}{\Omega_{\text{BZ}}} \frac{\omega_{j'}}{\sqrt{\omega_{j'}^2 + \Delta_{mk+q}^2(i\omega_{j'})}} \times [\lambda_{nk,mk+q}(\omega_j - \omega_{j'}) - \mu_c^*] \delta(\epsilon_{nk}). \quad (7)$$

To solve the anisotropic Migdal–Eliashberg equations, the EPW (electron–phonon Wannier, electron–phonon coupling using Wannier function)<sup>20,60,61</sup> and Wannier90<sup>62</sup> codes are utilized. The  $\text{sp}^2$ ,  $\text{p}_z$  orbitals of B atoms and  $\text{d}_{z^2}$ ,  $\text{d}_{x^2-y^2}$ ,  $\text{d}_{xy}$ , f orbitals of La atom are included in the projection of the Wannier basis with a uniform  $12 \times 12 \times 12$   $k$ -mesh. Furthermore, for the EPC interpolation, a  $k$ -grid of  $60 \times 60 \times 60$  and  $q$ -grid of  $30 \times 30 \times 30$  are used. Matsubara frequencies for fermions,  $i\omega_j = (2j + 1)\pi T$ , are set with a cutoff energy of 0.3 eV greater than four times of the maximum phonon energy. The effective Coulomb potential  $\mu_c^* = 0.1$  eV and convergence threshold less  $10^{-4}$  eV are used in solving the Eliashberg equations. To study topological properties, iterative surface Green's function and Wilson loop simulations are carried out *via* the WannierTools package<sup>63</sup> with the same tight-binding Wannier Hamiltonian.

## Data availability

The data that support the findings of this study are available from the authors upon reasonable request.

## Author contributions

H. T. J. conceived the project. C. H. C. and Y. S. L. carried out the DFPT calculations and topological analysis, respectively. A. H. supervised the calculations. All authors contributed to discussions and the final manuscript.

## Conflicts of interest

The authors declare no competing financial or non-financial interests.

## Acknowledgements

This work was supported by the Ministry of Science and Technology, Taiwan. H.-T. J. also thanks support from NCHC, CINC-NTU, AS-iMATE-109-13, and CQT-NTHU-MOE, Taiwan.
