Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

Measuring Masses of Large Biomolecules and Bioparticles

Using Mass Spectrometric Techniques

Prepared for the Analyst (review article)

Keywords: large protein complexes, bioparticles, ion source, mass analyzer, detectors,
mass measurement, mass assignment, mass resolution

Abstract

Large biomolecules and bioparticles play a vital role in biology, chemistry, biomedical science, and physics. Mass is a critical parameter for characterization of large biomolecules and bioparticles. To achieve mass analysis, choosing a suitable ion source is the first step and the instruments of detecting ions, mass analyzers and detectors, should also be considered. Abundant mass spectrometric techniques have been proposed to determine the masses of large biomolecules and bioparticles, and these techniques can be divided into two categories: The first category is to measure the mass (or size) of intact particles, including single particle quadrupole ion trap mass spectrometry, cell mass spectrometry, charge detection mass spectrometry, and differential mobility mass analysis; the second category aims to measure the mass and tandem mass of biomolecular ions, including quadrupole ion trap mass spectrometry, time-of-flight mass spectrometry, quadrupole orthogonal time-of-flight mass spectrometry and orbitrap mass spectrometry. Moreover, algorithms for mass and stoichiometry assignment of electrospray mass spectra are developed to obtain accurate structure information and subunit combinations.

1. Introduction

Mass spectrometric techniques can be applied to acquire masses and fragment of large biomolecules and of bioparticles which facilitate the study of biological process, interaction of biomolecules, and their structures and functions.¹⁻³ The size of large biomolecules and bioparticles are in the range from 1 nm to 100 μm . Those large biomolecules and bioparticles include protein complexes, viruses, bacteria and cells. So far, it is still a challenge to detect bioparticles with sizes from 20 nm to 100 nm.^{4,5} Many research groups have tried to develop mass spectrometers to detect the masses of these sizes. In general, a mass spectrometer includes an ion source, a mass analyzer and a detector and therefore selecting ion sources and designing workable mass analyzers and detectors are a necessity.⁶

Ions are a primary issue for mass analysis. The ion sources used in mass spectrometry (MS) for large ions include electrospray ionization (ESI)⁷, matrix-assisted laser desorption/ionization (MALDI)^{8,9} and laser-induced acoustic desorption (LIAD)¹⁰⁻¹². With ESI ion source, proteins, protein complexes and viral capsids are generated in air and kept intact in vacuum.¹³⁻¹⁷ ESI ion source can produce multiple charged ions with mass-to-charge ratio (m/z) below 100000. However, when the particle size becomes large, particles gain higher charges on the surfaces (typically $> 50+$) and cause highly overlapping ion series, making charge assignment

1
2
3
4 difficult.¹⁸⁻²⁰ By contrast, the MALDI ion source mostly generates singly, doubly
5
6 charged peaks which could be easily assigned. Intact ions can be produced by laser
7
8 irradiation on matrix crystal. When analyzing large ions, formation of particles is
9
10 found in the size range from 10 nm to 1000 nm by irradiating MALDI matrix
11
12 samples.^{21, 22} The matrix particles will interfere with viral particles (the size range
13
14 from 20 nm to 300 nm) during laser desorption process and thus hinder the analysis of
15
16 large bioparticles. Moreover, when the particle mass becomes large (>100 kDa), its
17
18 ion velocity is low, making high mass ion detection very challenging.²³⁻²⁵ Besides,
19
20 tandem mass analysis of MALDI ions is helpful to acquire the structure information,
21
22 but it is not well studied yet for $m/z > 12000$.²⁶ The LIAD ion source is favorable in
23
24 generating particles with the size greater than 50 nm by means of acoustic waves.^{12, 27,}
25

²⁸ Multiple pre-charged ions can be generated without matrix interference and fitted to single particle analysis with both optical and charge detection.^{12, 27} The drawback of LIAD ion source is low ion generation efficiency.

After ions are generated, they must be transported and guided to the mass analyzers for mass analysis. Typically, by reducing the guiding quadrupole driving frequency and increasing the buffer gas pressure, high mass ions can be cooled down and guided to mass analyzers.²⁹⁻³³ Mass analyzers can be divided into ion trap and time-of-flight categories. Ion trap mass analyzers such as two dimensional³⁴⁻³⁷ and

1
2
3
4 three dimensional quadrupole ion trap (QIT)^{38,39}, DC gate ion trap⁴⁰ and orbitrap^{31,32},
5
6
7 ⁴¹ show good trapping efficiency of large particles. Time-of-flight (TOF) mass
8
9
10 analyzers can be run in linear, reflectron, and orthogonal modes and coupled with
11
12 quadrupole for mass selection, ion activation and isolation.^{29,30} Moreover, no mass
13
14
15 analyzers can fully cover the whole size ranges of nanoparticles. If the particle density
16
17
18 is known, the particle size can be converted to particle mass. Therefore, differential
19
20
21 mobility analysis (DMA) coupled with electrospray ion source offers an alternative
22
23
24 approach to measure the effective particle sizes and thus characterize large
25
26
27 biomolecules and nanoparticles ranging from a few nanometers to several hundred
28
29
30 nanometers.⁴²⁻⁴⁴
31

32
33 Detectors are incorporated with mass analyzers to detect ions. The main reason
34
35
36 that the conventional mass spectrometers cannot detect high mass ions is the use of a
37
38
39 secondary electron detector, such as an electron multiplier and multi-channel plates
40
41
42 (MCP) which cause low secondary electron yields of high mass ions. New detectors
43
44
45 including a charge detector^{27,40}, a nanomembrane detector^{45,46}, a secondary ion
46
47
48 detector^{47,48}, an active pixel detector⁴⁹, and a cryodetector⁵⁰ are therefore designed
49
50
51 and incorporated with mass analyzers to overcome that problem.^{46,47,51,52}
52

53
54 In general, when determining the masses of large biomolecules and bioparticles,
55
56
57 we could divide mass spectrometric techniques into two categories. The first category
58
59
60

1
2
3
4 aims to measure the masses of intact particles including single particle quadrupole ion
5
6 trap mass spectrometry^{12, 28, 53}, cell mass spectrometry^{27, 54}, charge detection mass
7
8 spectrometry^{40, 55, 56} and differential mobility mass analysis^{42, 43}. In single quadrupole
9
10 ion trap mass spectrometry and cell mass spectrometry, detectors such as light
11
12 scattering, laser induced fluorescence, a charge detector and an electron multiplier are
13
14 developed to overcome the detection limit of large biomolecules and bioparticles.
15
16 Charge detection mass spectrometry adopts a non-destructive charge detector to sense
17
18 the image charge of particles. Differential mobility mass analysis employs the
19
20 condensation particle counters (CPCs) to optically detect nanoparticles. The second
21
22 category focuses on the mass and tandem mass measurement of biomolecular ions
23
24 including quadrupole ion trap mass spectrometry⁵⁷⁻⁵⁹, time-of-flight mass
25
26 spectrometry^{23, 24, 46}, quadrupole orthogonal time-of-flight mass spectrometry^{29, 30} and
27
28 orbitrap mass spectrometry^{31, 32, 41}. Quadrupole ion trap mass spectrometry uses an
29
30 electron multiplier to acquire mass spectra of large proteins. Time-of-flight mass
31
32 spectrometry couples with several detectors including a microchannel plate detector, a
33
34 secondary ion detector, a cryogenic detector, a nanomembrane detector, and a charge
35
36 detector to extend the detection limit of large proteins. Quadrupole orthogonal
37
38 time-of-flight mass spectrometry and orbitrap mass spectrometry can perform tandem
39
40 mass analysis and high mass resolution analysis.

1
2
3
4 Quadrupole orthogonal time-of-flight MS and orbitrap MS now play important
5
6
7 roles in native mass spectrometry.¹ Large viral capsids, such as hepatitis B virus
8
9
10 capsids and their fragmental ions are acquired with quadrupole orthogonal TOF MS.^{19,}
11
12
13 ⁶⁰ Orbitrap MS is now able to analyze large protein complexes up to 1 MDa and its
14
15 tandem MS ability achieves MS³ with high mass resolution.^{31,32} The high quality
16
17 mass spectra enable high throughput study of large ESI ions. To streamline the
18
19 identification of mass, stoichiometry and interactions of different subunits, new
20
21 algorithms, such as AutoMass¹⁹ and Massign,²⁰ are developed.

30 **2. Ion Sources**

31 2.1 Electrospray ionization

32
33
34
35 Dole *et al.* developed electrospray ionization to generate molecular beam of
36
37 macroions.⁶¹ Polystyrene macroions of molecular weight up to 411000 weight-
38
39 average amu appear mostly to be multiply charged single species. An important
40
41 milestone was hit by Fenn *et al.* who applied ESI technique to generate
42
43 oligonucleotides and proteins and proteins with molecular weights up to 130000 Da
44
45 were obtained.⁷ Robinson *et al.* performed impressive mass measurement of
46
47 bacteriophage MS2 viral capsid ions up to 2.5×10^6 Da and with a charge state of
48
49 ~ 113 .⁶² Bacteriophage MS2 viral capsids remained intact during their flight and were

2.2 Matrix-assisted laser desorption ionization

Tanaka *et al.* first generated polymer and proteins up to m/z 100000 with soft
laser desorption/ionization of nanogold powder dispersed in glycerol and acquired the
mass spectra.⁸ Karas and Hillenkamp reported matrix-assisted laser desorption
ionization by ultraviolet irradiation could obtain mass spectra of proteins.⁹
Hillenkamp *et al.* further used infrared laser to acquire mass spectra of synthetic DNA,
restriction enzyme fragments of plasmid DNA, and RNA transcripts up to a size of
2180 nucleotides.²⁵ Li *et al.* generated polymers up to 1.5 MDa and detected the
doubly charged ion signals.²³ Not only polymers and proteins can be generated by
MALDI ion source, but also nanomaterials can be formed in the gas phase, ZnS⁶⁵ and
Pt⁶⁶ nanoparticles were detected with a TOF mass spectrometer. Low charge states of
MALDI ions make the mass assignment simple and straight-forward.

2.3 Laser-induced acoustic desorption

Laser-induced acoustic desorption (LIAD) can generate large ions. Chen *et al.* adopted LIAD to desorb 20 μm size Al_2O_3 particles and cytochrome C protein from sapphire substrate.¹⁰ In addition, surface acoustic waves can detach particles from sample substrate surface and improves cleaning effectiveness as shown by Kolomenskii *et al.*⁶⁷ Viral particles, bacteria and cells are desorbed by LIAD with quadrupole ion trap mass spectrometry.^{12, 27, 28}

3. Instrumentation

3.1 Quadrupole ion trap mass spectrometry and linear ion trap mass spectrometry

Quadrupole ion trap (QIT) is a suitable ion trap device for non-destructive mass measurement of single, trapped nanoparticles and for destructive mass measurement of large ions. The non-destructive mass measurement can be traced to 1950s.⁶⁸ Single microparticles were trapped and analyzed by light scattering, laser induced fluorescence, and charge detection methods. The destructive mass measurement is done with an electron multiplier and a charge detector. To eject ions, “mass selective instability” mode is applied in a quadrupole ion trap. Either rf amplitude or frequency must be scanned to acquire the mass spectra. Frequency-scan employs the wideband power amplifier, so it can easily cover wide mass range. Voltage-scan needs a power

1
2
3
4 amplifier to boost a transformer to several thousand volts. Due to high Q factor of a
5
6 transformer, it is very difficult to cover wide mass range with voltage-scan. Therefore,
7
8 frequency-scan is superior to voltage-scan.^{54, 57, 69}
9
10

11 The advantage of linear ion trap (LIT) is its high ion capacity and MSⁿ ability.^{34,}

³⁸ LIT is favorable to store more ions and allows tandem analysis of trapped ions. An electron multiplier and high buffer gas pressure would affect bioparticle detection with LIT.⁷⁰ High buffer gas is needed to cool down ions when the size of ions becomes larger, but an electron multiplier could not be operated in this condition.

Typically conversion dynode voltage must be set high enough (> 10kV) to get high gain of ion signals, but high buffer gas pressure will cause discharging of an electron multiplier. A charge detector coupled with LIT-MS can work at high pressure condition without discharging problem and thus enhance the detection of high mass ion signals.

3.1.1 Electron multiplier

The sensitivity of a secondary electron detector (e.g. an electron multiplier and microchannel plates) decreases as $v^{4.4}$, where v is the velocity of the incident ion.^{45, 46}

This velocity relation leads to a remarkable decrease in sensitivity of those detectors for large and heavy ions. To detect high mass MALDI ions with an electron multiplier,

1
2
3
4 Schlunegger *et al.* firstly adopted three dimensional QIT with frequency-scan method
5
6 to cover high mass range.⁵⁷ By using low frequencies (below 100 kHz) and low
7
8 amplitudes (below 200 V), high mass singly charged bovine serum albumin (BSA)
9
10 and immunoglobulin G (IgG) ions are trapped and analyzed by frequency sweep
11
12 method. The instrument shows good sensitivity, signal-to-noise ratios (10:1), and a
13
14 mass resolution of 70. Ding *et al.* proposed using a frequency-scan digital ion trap
15
16 coupled with electrospray ionization (ESI) and atmospheric pressure matrix-assisted
17
18 laser desorption/ionization (AP-MALDI) sources to demonstrate the capability of the
19
20 digital method.⁶⁹ AP-MALDI mass spectra of singly charged horse heart myoglobin
21
22 ions (17 000 Th) were generated using a trapping voltage of only 1000 V and a mass
23
24 resolution of 2100 is reached. Recently, McLuckey *et al.* developed mass-selective
25
26 instability analysis by scanning a direct current (dc) voltage applied to the end-cap
27
28 electrodes while holding the radio frequency (rf) potential at a fixed value in a QIT.⁵⁹
29
30 They ejected ions along the $\beta_z = 0$ instability line in the direction from high
31
32 mass-to-charge (m/z) to low m/z . Doubly charged pyruvate kinase ions were observed
33
34 at $m/z \sim 131\ 000$. The combination of QIT and an electron multiplier detector suffers
35
36 from poor ion-secondary electron conversion efficiency and low ion ejection velocity
37
38 and therefore the ion detection efficiency of high mass ions is poor.
39
40

55
56 Commercial LIT MS operated in the frequency of ~ 1 MHz can detect mass
57
58
59
60

1
2
3
4 range up to $m/z \sim 4,000$. In order to extend mass range of LIT MS, Chen *et al.*
5
6 developed a home-made frequency-scan LIT mass spectrometer with low rf driving
7
8 frequency. They adopted frequency-scan method to cover the wide mass range and
9
10 raised the conversion dynode voltage up to -30 kV to increase secondary electron
11
12 signals. Singly charged secretory immunoglobulin A (385 kDa) ions were detected.
13
14
15
16
17
18 Reilly *et al.* demonstrated singly-charged, intact proteins in the range of 10 to 200
19
20 kDa and 1.5 MDa urea particles can be detected by a linear quadrupole ion trap.
21
22

23 3.1.2 Light scattering

24
25
26
27 Photon is a fundamental light particle and used by light scattering method to
28
29 detect ions because of its high sensitivity. Millikan's oil drop experiment is the first
30
31 one to measure charges of microparticles by light scattering method.⁷¹ Wuerker *et al.*
32
33 demonstrated the capability of trapping and detection of single microparticles using a
34
35 QIT mass spectrometer.⁶⁸ Hars and Tass further proposed measuring the star-like ion
36
37 motion in the radial plane to determine the mass of a single particle in the range of
38
39 10^9 - 10^{12} Da with accuracy of 10^{-3} ;⁷² however, changes in charge states are not obvious
40
41 because of multi-particle clumping during the injection of ions. Schlemmer *et al.*
42
43 developed fast Fourier transform technique to measure the single particle mass at r-z
44
45 plane.^{73, 74} 500 nm SiO₂ particles were trapped in an ion trap with resolution (mass
46
47 deviation) of 10^{-4} in a 10 s measurement. Cai *et al.* further used QIT to trap and eject
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 microparticles, and ions were detected via light scattering method.^{75,76} Single particle
5
6
7 mass spectra were acquired in mass-selective instability mode. But absolute charge
8
9
10 states of trapped particles were not known in this study. Peng *et al.* observed a
11
12 stationary star pattern by fine-tuning driving frequency to resonate with the radial
13
14 secular frequency in a QIT and obtained an analytical formula of secular frequency
15
16 that is valid for $q_z < 0.8$.^{12,53} Intact single *Escherichia coli* cells were generated by
17
18 MALDI ion source and their absolute mass was measured.⁵³ Besides, with laser
19
20 induced acoustic desorption (LIAD) ion source, viruses, bacteria, and mammalian
21
22 whole cells can be generated without confusion caused by MALDI clusters. The m/z
23
24 of a particle can be measured with very high precision up to 10^{-4} .^{77,78} The QIT MS
25
26 adopted an averaging peak-to-peak voltage detector to measure rf amplitude which is
27
28 traced to a standard rf source and therefore QIT MS can be used as particle mass
29
30 standard measurement with the particle size greater than 300 nm.⁷⁸
31
32

33
34
35
36
37
38
39
40
41 Trevitt *et al.* combined the secular frequency measurement with Mie scattering
42
43 measurement of single particle and found small uncertainties in secular frequency
44
45 measurement resulted in significant errors in the absolute mass and charges. But the
46
47 misalignment of QIT electrodes is small and trap parameter z_0 is appropriate.⁷⁹ To
48
49 overcome low light collecting efficiency of QIT, Nie *et al.* used a cylindrical ion trap
50
51 (CIT) to replace the end-cap electrodes by an electrically conductive glass plate that
52
53
54
55
56
57
58
59
60

5
6
7 successfully detected recombinant human adenovirus type 5 (Ad5), grouper iridovirus
8
9
10 (GIV), and vaccinia virus (VV) with sizes range from 80 to 300 nm.²⁸
11
12
13

14 15 3.1.3 Laser induced fluorescence 16

17
18 Laser induced fluorescence (LIF) is widely used in flow cytometry to measure
19
20 the size distribution of nanoparticles. Cai *et al.* firstly attempted to integrate the LIF
21
22 with QIT to confine single particles with mass larger than 5 MDa in a trap.⁸⁰ They
23
24 successfully observed individual fluorescent 27 nm nanospheres which contains 180
25
26 fluorescein dye equivalents and an average signal-to-noise ratio of 10 has been

Laser induced fluorescence (LIF) is widely used in flow cytometry to measure the size distribution of nanoparticles. Cai *et al.* firstly attempted to integrate the LIF with QIT to confine single particles with mass larger than 5 MDa in a trap.⁸⁰ They successfully observed individual fluorescent 27 nm nanospheres which contains 180 fluorescein dye equivalents and an average signal-to-noise ratio of 10 has been achieved. Moreover, they adopted another QIT to cool nanoparticles inside the QIT and monitor LIF of trapped particles to acquire the mass spectra of single particles.^{58,}

⁸⁰ This configuration extended the mass analysis of nanoparticles with $m/z > 10^5$.⁵

Recently, Talbot *et al.* used LIF to visualize populations of gaseous ions stored in a quadrupole ion trap (QIT) mass spectrometer. This technique might help understand the collective ion motion and the ejection behavior of high mass ions under high buffer gas pressure.⁸¹

3.1.4 Charge detector

1
2
3
4 Single particle QIT mass spectrometry can measure intact bioparticles, including
5
6
7 viruses, bacteria, and whole mammalian cells with high precision.⁴ But it takes about
8
9
10 15–30 minutes to determine the absolute mass of each trapped particle. Peng *et al.*
11
12
13 first proposed charge-monitoring laser-induced acoustic desorption mass spectrometry
14
15 (CMS) for rapid mass measurement of cells and microparticles.^{27, 54} The CMS
16
17
18 simultaneously measure both the mass-to charge ratio (m/z) and total charges (z) of a
19
20
21 particle. Typically more than 5 particles with S/N ratio of 10 are acquired in one
22
23
24 second. The background noise of the charge detector is about 500 e. CMS
25
26
27 successfully measured different types of mononuclear cells ($CD3^+$ lymphocytes and
28
29
30 $CD14^+$ monocytes) and cancer cells. Nie *et al.* followed this approach to acquire mass
31
32
33 and mass distributions of different red blood cells.⁸² Mass resolution of ~ 100 and
34
35
36 mass accuracy of $\sim 1\%$ can be achieved with this frequency-scan CMS.⁸³ Chen *et al.*
37
38
39 measured the mass distribution of sinapinic acid matrix clusters from monomer to
40
41
42 MDa region with a CMS.²² In CMS, harmonic interference noises from an AC power
43
44
45 source and rf voltage interference noise from rf field affect the detection of a charge
46
47
48 detector. Chou *et al.* proposed an orthogonal wavelet packet decomposition (OWPD)
49
50
51 filtering approach to denoise interference from the acquired mass spectra. Mass
52
53 spectra of microparticles and *Escherichia coli* are obtained without rf interference.⁸⁴
54
55
56 When rf is applied on a QIT in high pressure condition (~ 80 mTorr), undesired arcing
57
58
59
60

1
2
3
4 is produced; therefore, Xiong *et al.* adopted rectangular and triangular waveforms to
5
6
7 reduce the onset voltage and found their mass resolution is the same as that of
8
9
10 conventional sinusoidal waveform.⁸⁵ Moreover, rectangular waveform technique can
11
12 detect large ions with a digital ion trap,⁶⁹ which fosters the development of miniature
13
14 instrument with switching circuits instead of power amplifier. The power of CMS
15
16 instrument can be greatly reduced. To reduce the size of ion trap, Nie *et al.* have
17
18 shown that a miniature cylindrical ion trap mass spectrometer (CIT-MS) equipped
19
20 with a mechanical pump can measure the masses of cells and microparticles.⁸⁶
21
22
23
24
25
26

27 In applications, CMS is used to measure the quantity of nano-/microparticles as
28
29 efficient carriers for drug delivery.^{87, 88} Quantitative measurement of the cellular
30
31 uptake of nano-/microparticles is of great importance for the elucidation of the
32
33 mechanisms of cell endocytosis and exocytosis. We found CMS could be used to
34
35 measure not only the cellular uptake of metal nanoparticles but also that of nonmetal
36
37 nano-/microparticles and greatly reduced analysis time as compared to conventional
38
39 approaches such as inductively coupled plasma mass spectrometry (ICP-MS) which
40
41 limits to metal nanoparticles. Nie *et al.* used CMS to characterize the column packing
42
43 materials in high-performance liquid chromatography (HPLC).⁸⁹ The mass deviation
44
45 of the silica particles after modification by different length of alkyl chains can also be
46
47 determined using CMS. The specific surface area, carbon load, and size distribution
48

1
2
3
4 of packing materials are characterized simultaneously too. Nie *et al.* showed CMS can
5
6 be incorporated with an ambient desorption source to measure masses of
7
8
9 microparticles.⁹⁰ The ambient desorption method exploited the discontinuous
10
11 atmospheric pressure interface (DAPI) to generate and desorb microparticles under
12
13 atmospheric pressure with a pulsed airflow as shown in Figure 1. Bacteria, cells,
14
15 polystyrenes, synthetic diamonds, and silica particles can be directly desorbed in
16
17
18
19 ambient condition.
20
21
22
23

24 Furthermore, a charge detector can measure the quantity of molecules. Peng *et al.*
25
26 first measured the C₆₀ signals with a QIT MS.²⁷ Chen *et al.* measured IgG and IgM
27
28 ions.⁹¹ To increase the number of ions and ion signal, a possible way is to incorporate
29
30 a charge detector with LIT-MS.
31
32
33
34
35
36
37
38

39 3.2 Time-of-flight mass spectrometry

40
41 MALDI ion source is frequently coupled with time-of-flight (TOF) mass
42
43 spectrometer.⁹² The mass range of TOF MS should be unlimited in theory; however,
44
45 its mass range is limited by the sensitivity of a detector in practice. Conventional
46
47 secondary electron detectors, e.g. MCP are incorporated with TOF MS and the
48
49 detection limit is < 1 MDa. Secondary ion detectors, cryogenic detectors, and
50
51
52
53
54
55
56 nanomembrane detectors are proposed to overcome the detection limit of TOF MS
57
58
59
60

1
2
3
4 and now are able to detect ions with mass > 1 MDa.
5
6
7

8 9 10 3.2.1 Microchannel plates

11
12 The microchannel plate detector is widely used in TOF MS. Detection of human
13 IgM at m/z approximately 1 MDa is achieved by Williams *et al.*²⁴ Li *et al.* further
14 demonstrated the detection of doubly charged polystyrene signals with molecular
15 weight up to 1.5 million.²³ But the signal-to-noise ratio is poor and close to upper
16 limit of a MCP detector. To enhance the sensitivity of a MCP detector, Heeren *et al.*
17 developed an active pixel detector (MCP-based detection system). The S/N ratio can
18 be improved to a factor of ~ 4 in detecting IgA molecules.⁴⁹

36 3.2.2 Secondary ion detector

37
38 A Daly detector is a gas ion detector which consists of a metal doorknob, a
39 scintillator (phosphor screen) and a photomultiplier.⁹³ It was widely used in mass
40 spectrometers. Zenobi *et al.* collected the photons produced by the impact of ion
41 packets with a scintillator and demonstrated that an ion-to-photon detector showed
42 about 10 times higher signals than the MCP for heavy ions (150 kDa).⁴⁸ Wang *et al.*
43 further developed a bipolar ion detector (BID) to detect secondary ions rather than
44 secondary electrons with a conversion dynode voltage at -25 kV. For ions with $m/z \sim$

5
6
7
8

9 10 3.2.3 Cryogenic detector

11
12 Phonons are elementary excitations of crystal lattice. When ions impinge the
13 cryogenic detector, heats are generated and transferred to collective vibrations on
14 normalinsulator-superconductor (NIS) microcalorimeter device near absolute zero
15 temperature.⁹⁴ A very small change in temperature resulting from interaction of NIS
16 microcalorimeter device and a particle leads to a significant change in resistance. The
17 junction current is measured by a high-speed low-noise series-array superconducting
18 quantum interference device (SQUID) preamplifier. Measuring the phonons is
19 therefore dependent on the energy not on particle masses and velocity of ions. Frank
20 *et al.* introduced a low-temperature calorimetric detector to measure kinetic energy of
21 individual incident ions irrespective of their masses or charge state.^{95, 96} Cryogenic
22 microcalorimeters and superconducting tunnel junctions are velocity independent and
23 phonon of ions at temperatures lower than hundred millikelvin are measured.
24
25 Recently, Zenobi *et al.* showed a 16-element superconducting tunnel junction (STJ)
26 detector coupled with a fully adjustable gimbal-mounted ion source/focusing region
27 can allow unparalleled sensitivity for detection of singly charged immunoglobulin M
28 ions (~1MDa).⁹⁷ Bier *et al.* further used the same 16 STJs detector and detected

4 polystyrene ions and virus capsids up to 2 MDa and 13 MDa, respectively.^{98, 99} These
5
6
7 cryogenic particle detectors show good mass sensitivity at high mass range, but the
8
9
10 drawbacks of cryogenic detectors are expensive cryogenic cooling unit, low active
11
12
13 detection areas and long response time, and thus restrict their practical use.
14
15
16
17

18 3.2.4 Nanomembrane detector 19

20
21 A nanomembrane detector based on mechanical deformation and vibration of a
22
23
24 nanomembrane is developed to overcome the detection of high mass ions by Blick *et*
25
26
27 *al.*^{45, 46} Figure 2 shows the schematic design of nanomembrane detector with TOF MS.
28
29
30 Mechanical vibrations of the nanomembrane excited by ion bombardment translate
31
32
33 into corresponding oscillations in the field emission current. The modulated field
34
35
36 emission current is amplified by the microchannel plate (MCP). High mass proteins
37
38
39 such as IgG and IgM are measured with high mass resolution of 129±44 and 250±48.
40
41
42 In the right inset of Figure 2,⁴⁵ the mass resolution ($m/\Delta m$) becomes better as
43
44
45 molecular mass is increasing, which is because the rise time and decay constant are
46
47
48 highly independent on both mass and kinetic energy of the ion, and the time
49
50
51 resolution is highly dependent on the effective cooling of the silicon nanomembrane
52
53
54 via field emission.
55
56
57
58
59
60

3.2.5 Charge detector

Hillenkamp *et al.* developed a charge detector for ion detection in MALDI-TOF instruments. The charge detector comprises a 18 mm-diameter metal electrode as a Faraday charge collector and a charge-sensitive FET preamplifier. A net charge of 1.8×10^4 is required for S/N ratio of 2. IgG ions can be detected with S/N ratio > 10 . With rise time of 25 ns, mass resolution for MALDI ion detection is not restricted to a charge detector. To increase the sensitivity of a charge detector, Bouyjou *et al.* developed a 16-channel low power CMOS device and reached an equivalent noise charge of $318 e^-$.¹⁰⁰

3.3 Charge detection mass spectrometry

Charge detection mass spectrometry (CDMS) measures the image charge of ions. Image charge detection of microparticles was first reported in 1960 by Shelton *et al.*, who used pairs of conducting metal plates inside a shielded cylinder to detect charged iron spheres in a high voltage accelerator system.¹⁰¹ With known time-of-flight of ions, absolute masses of ions thus can be calculated. To measure the absolute masses of particles accurately, two types of measurement were developed to increase the signal-to-noise ratio. First is the recirculating trap which allows multiple paths of ions in an electrostatic DC ion trap.⁴⁰ Second is the linear array which can extend the

1
2
3
4 detection limit by $\sqrt{2}$ with multiple sensing stages.⁵⁶
5
6
7

8 9 10 3.3.1 Recirculating trap

11
12 Benner designed a gated electrostatic ion trap that can repetitiously measure the
13 charge and m/z of large electrospray ions.⁴⁰ The schematic design of this instrument is
14 shown in Figure 3. Once a single ion passing through the detector tube, the detector
15 displays an amplifier noise of 50 electrons. After averaging, noise can be reduced to 5
16 electrons. Jarrold *et al.* showed cooling of the JFET can increase its transconductance
17 and lower thermal noise, and thus improve the signal to noise (S/N) ratio.⁵⁵ Single
18 ions with 9 elementary charges have been detected while ADH monomer ions with 32
19 to 43 charges were trapped over 1500 cycles and the measured image charge is around
20 2.2 electrons. With CDMS, Jarrold *et al.* further measured the mass (23.6 MDa) and
21 charge (427e) of bacteriophage P22 procapsids¹⁰² and detected intermediates of
22 hepatitis B virus capsids¹⁰³.

44 3.3.2 Linear array

45
46
47 Another thought to reduce noise is to arrange charge detectors in series. In Figure
48 4, Gamero-Castano *et al.* showed the design and carefully calculated its charge
49 detection limit.⁵⁶ The detection limit and standard error of the charge measurement
50 can be reduced by factors of $\sqrt{2}$ and \sqrt{n} . Measurement of a droplet with time of

6
7

8 9 10 3.4 Differential mobility analysis

11
12 Differential mobility analysis (DMA) is a routine analysis method used to
13 rapidly characterize viruses and virus-like particles.^{42, 44} A DMA device is composed
14 of four major elements: a gas flow, a neutralizer, an electric field which is generated
15 by two flat electrodes and perpendicular to the gas flow, and a condensation particle
16 counter (CPC) placed at the end of one electrode for particle detection as depicted in
17 Figure 5.⁴³ In a DMA device, a charged particle is driven by two forces, drag force
18 (related to gas flow, particle drift, and particle size) and electric force (generated by
19 the interaction between electric field and particle charge). Specific particles can drift
20 into CPC in exact conditions; therefore, DMA is capable of separating charged
21 particle based on their m/z or gas-phase electrical mobility.⁴² Unlike typical MS
22 analyzers, drag force provides a big effect on particle motion because DMA is
23 operated at near atmospheric pressure with gas flow. So, the information of particle
24 sizes can be offered by DMA analysis.

47
48
49

50 Charge reduced electrospray differential mobility analysis (ES-DMA) can
51 quantitatively analyze particle sizes from 0.7 to 800 nm. The notable precision of 24
52 nm particles separated by ES-DMA is 1.2 nm (standard derivation).¹⁰⁴ The ES-DMA
53
54
55
56
57
58
59
60

1
2
3
4 is suitable for size analysis of whole viruses and virus fragments. For instance, S.
5
6
7 Guha *et al.* measured the PR772 and PR7 with ES-DMA, and the mean sizes were
8
9
10 determined to be 62.1 ± 0.4 nm and 23.0 ± 0.3 nm, respectively.¹⁰⁵ Hogan *et al.* also
11
12 analyzed bacteriophage MS2 and found its diameter was 24.13 ± 0.06 nm while the
13
14 capsid heads of large bacteriophages T2 and T4 $88.32 \text{ nm} \pm 1.02$ nm and 87.03 ± 0.18
15
16 nm, respectively.⁴³ Besides, ES-DMA has capability of measuring the concentration
17
18 of virus in solution. Cole *et al.* determined the particle concentration of three
19
20 bacteriophages MS2, PP7, and ϕ X174 which were similar to amino acid analysis in
21
22 most cases.¹⁰⁶

29
30
31
32

33 3.5 Quadrupole orthogonal time-of-flight mass spectrometry 34 35

36 Using nanoflow electrospray with time-of-flight mass analysis, Robinson *et al.*
37
38 showed that it is possible to obtain definitive charge states in the spectra of large
39
40 multiprotein complexes.¹⁰⁷ In Figure 6a, GroEL complex shows a series of peaks
41
42 centered at m/z 10000. Next, bacteriophage MS2 was proved to maintain the intact
43
44 capsid in vacuum and had undergone collision-induced dissociation (CID) with
45
46 neutral gas molecules and the CID mass spectrum was shown in Figure 6b.⁶² Heck *et*
47
48 *al.* further modified the Q-TOF 1 instrument including the introduction of enhanced
49
50 pressure and altered electronics (e.g. quadrupole frequency, collision energy and TOF

4 pusher frequency), as well as specialized detectors to improve transmission and
5
6 measurement of very large ions.³⁰ The instrument design is shown in Figure 7. HBV
7
8 capsids of 90 and of 120 dimers with masses of 3 and of 4 MDa were determined
9
10 from m/z 20000 to 30000.^{60, 108} The measured precision of both capsids is within
11
12 0.1%. 10.1 MDa norwalk virus-like particles were measured as a function of solution
13
14 pH, ionic strength, and capsid protein concentration.⁶³ Figure 8 shows the intact 18
15
16 MDa capsids of bacteriophage HK97 measured with modified Q-TOF 1 instrument
17
18 with a charge number of 350.⁶⁴ It is noted that incomplete desolvation of specimen
19
20 causes the peak separation and overlapping around 40 GDa which limits the detection
21
22 of large protein complexes from GDa to MDa.

35

36 3.6 Orbitrap mass spectrometry

37
38 With an orbitrap mass analyzer, intact protein assemblies with molecular weight
39
40 approaching one million Daltons were measured by Cooks⁴¹ and Heck *et al.*^{31, 109}
41
42 Since the introduction of the first orbitrap-based mass spectrometer in 2006, this mass
43
44 analyzer has become increasingly popular.¹¹⁰⁻¹¹² The orbitrap mass spectrometers are
45
46 used to analyze small molecules and peptides, but now these instruments can be
47
48 modified to analyze very large native protein assemblies. Shown in Figure 9 is a
49
50 dedicated instrumental modifications of an Exactive Plus instrument (ThermoFisher

57
58
59
60

1
2
3
4 Scientific) with a higher-energy collision-induced dissociation (HCD) option. Briefly,
5
6 the modifications include altering software to allow detection of ions at higher m/z
7
8 range, tuning radiofrequency voltages of transport multipoles and altering the pressure
9
10 in the HCD cell. CsI clusters up to m/z of 18,000 were detected and a resolution of
11
12 25,000 was achieved at m/z of 5,000 and a resolution of 16,000 was obtained at m/z of
13
14 10,000. The full width at half maximum (FWHM) resolution of GroEL peaks (68+ to
15
16 77+ at m/z of 10,000 to 12,000) was close to 4,000, and the experimental molecular
17
18 weight was close to 1 MDa. Moreover, glycoforms for an antibody-based construct
19
20 with a very heterogeneous glycan pattern were resolved and assigned.¹⁰⁹ A few
21
22 femtomoles of samples were required and data acquisition of single mass spectrum
23
24 was in few seconds. A resolution up to 12000 at m/z 6000 could be achieved with
25
26 high mass accuracy ($\sim 0.001\%$), thus allowing the assignment of modified antibodies.
27
28 Kelleher and Makarov *et al.* further modified the Q Exactive plus instrument with
29
30 orthogonal ion injection interface, two ion funnels, a quadrupole filter and a high
31
32 pressure HCD cell (10^{-2} mbar).³² The signal-to-noise ratio can be enhanced with
33
34 orthogonal ion injection and ion funnels and the injection time was greatly reduced.
35
36 The ion transmission was extended to m/z 20000 and ions can be mass-selected in this
37
38 mass range. Isolation window was about 70 in the m/z range exceeding 10000 Th.

6
7

8 9 10 **4. Algorithms**

11
12 Electro spray ionization coupled to native mass spectrometry (MS) has evolved as
13
14 an important tool in structural biology to decipher the composition of protein
15
16 complexes.^{1, 20, 113} Commercial MS software was successfully developed to
17
18 investigate and assign mass spectra of proteins or peptides. It is proper for the
19
20 identification of charge state series of protein complexes as the charge state series are
21
22 sufficiently separated. However, overlapping charge state distributions, fine structure
23
24 and peak broadening of heterogeneous samples hamper mass analysis. To facilitate
25
26 mass analysis, theory development and automation in the pre-processing of raw mass
27
28 spectra, assigning peaks to ion series and deciphering the subunit compositions are
29
30 discussed as below.
31
32
33
34
35
36
37
38
39
40
41
42
43

44 **4.1 Theory**

45
46 Conventional approach to assign ESI mass spectra of proteins was first invented
47
48 by Mann *et al.* They developed the first averaging and deconvolution algorithm to
49
50 assign charge states in ESI mass spectra of protein complexes.¹¹⁴ The “averaging
51
52 algorithm”, assigns charge numbers to the ions associated with the m/z value for each
53
54
55
56
57
58
59
60

1
2
3
4 peak and averages the resulting masses to give a best estimate of the molecular
5
6 masses. The “deconvolution algorithm”, transforms several peaks of multiply charged
7
8 ion into one peak corresponding to a singly charged ion as shown in Figure 10.
9

10
11 Moreover, maximum entropy approaches are often used to find the best assignment
12
13 and reduce the complexity in the spectra based on deconvolution algorithm.¹¹⁵⁻¹²⁰
14
15

16
17 These approaches are useful to analyze proteins of intermediate masses, but are not
18
19 able to correctly assign charge states of larger protein complexes, e.g. viral capsids or
20
21 nano-/microparticles. Peng *et al.* introduced an LeastMass algorithm which is able to
22
23 achieve the charge states assignment of very high mass ions created by ESI.¹⁸ This
24
25 algorithm searches a series of m/z peaks which can match the charge ratio as input
26
27 and the molecular mass are obtained by taking into account all possible charge states.
28
29

30
31 The plot of $S/\langle m \rangle$ vs. z or $\langle m \rangle$, where S is the standard deviation, z is the ion charge,
32
33 and $\langle m \rangle$ is the mean mass, shows a periodic pattern when the correct charge
34
35 assignment is identified. The periodic pattern could be explained with the minimum
36
37 standard deviation theory, in which a harmonic oscillation indicates a correct charge
38
39 state assignment. Shown in Figure 11 is the analysis of HBV capsids. The periodic
40
41 pattern is observed in $T=3$ and $T=4$ ions when the correct charge is matched.
42
43
44
45
46
47
48
49

50
51 However, a selection of mixture peaks of $T=3$ and $T=4$ ions results in the loss of
52
53 periodicity. LeastMass can also help assign the correct charge states of single plasmid
54

9
10

11 12 13 14 15 4.2 Raw data processing 16

17
18 Raw data processing is of importance to reduce analysis time. An algorithm that
19
20 can handle noisy raw mass spectra is necessary. The data pre-processing requires
21
22 thorough smoothing, background subtraction, and an automatic threshold
23
24 determination. This is especially challenging when the signals are highly deformed
25
26 and mixed with noises.¹⁹ The automatic pre-processing software can greatly reduce
27
28 analysis time and keep fidelity of acquired mass spectra.
29
30
31
32
33
34
35
36
37

38 39 4.3 Search engine 40

41
42 A search engine, AutoMass, was developed by Peng *et al.* to automatically assign
43
44 ion series to peaks by game theory.¹⁹ AutoMass can define the correct boundary
45
46 between different distributions to yield accurate masses. It helps analyze the masses
47
48 and the boundary of heterogeneous protein assemblies with overlapping charge state
49
50 distributions, fine structure, and peak broadening. The boundaries of ion series in the

4 of the mass spectrum from CRISPR-related cascade protein complex are accurately
5
6 assigned. In Figure 12, complicated tandem mass spectra derived from intact HBV
7
8 capsids at high collision energy conditions are analyzed. The generated HBV tandem
9
10 mass spectra of $T = 3$ and of $T = 4$ precursor ions with an accelerating voltage of 400
11
12 V are depicted in Figure 12a,c, and tandem mass analysis by AutoMass are shown in
13
14 Figure 12b,d, respectively. The deviation of the predicted and the measured oligomer
15
16 masses is less than 0.03%, far less than a single protein subunit. Moreover, less
17
18 well-resolved mass spectra, for example, the norovirus capsid mass spectra at
19
20 different levels of desolvation are analyzed as well.

32

33 4.4 Subunit complexes assignment

34
35 Morgner *et al.* introduced Massign to optimize data analysis by reducing spectra
36
37 size, smoothing and subtracting background, identifying peaks, assigning ion series
38
39 and the number of possible subunit combinations by integrating information from
40
41 multiple sources.²⁰ By adding connectivity and stoichiometry restraints into the
42
43 software, Massign reduces the number of potential complexes to one or two as shown
44
45 in Figure 13. In practice, the ion boundary has to be manually refined and potential
46
47 mass range, m/z range, and maximum possible charge are needed to be inputted
48
49 manually. Benesch *et al.* developed CHAMP software which can estimate the
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 distribution of different stoichiometries from overlapping and unresolved peaks.¹²³ It
5
6 is similar to SOMMS¹²⁰ but is more user-friendly. Thalassinos *et al.* developed the
7
8 Amphitrite software,¹²⁴ which is favorable to analyze ion mobility data and is
9
10 comparable to CHAMP and SOMMS in peak assignment. It can retrieve or compare
11
12 different ion shapes from very complex samples.

21 **5. Choice of mass spectrometer**

22
23
24 The mass spectrometric techniques are summarized in table 1. In the following,
25
26 we will discuss how to choose a proper mass spectrometric technique. Firstly, to
27
28 measure masses of microparticles (e.g. cells), a quadrupole ion trap with a charge
29
30 detector would be favorable because it can measure masses and mass distribution of
31
32 cells in a short period of time.²⁷ Besides, it can measure mass difference before and
33
34 after cellular uptake of nanoparticles and adhesion of molecules on microparticle
35
36 surfaces and columns.^{87, 89} Secondly, a quadrupole ion trap with light scattering can
37
38 measure masses of single virus, bacteria and cells with high precision.^{12, 53} With this
39
40 technique, changes in mass due to adhesion of molecules on single
41
42 nano-/microparticles in vacuum can be studied. Thirdly, charge detection mass
43
44 spectrometry can measure the masses of viruses;^{14, 103} however, multiple charge nature
45
46 of ESI causes wide mass distribution of ions and limits its application. Fourthly, ESI
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 differential mobility analysis (DMA) is an alternative instrument to acquire the size
5
6 distribution of nanoparticles rapidly.⁴³ Fifthly, orbitrap^{31, 41} and orthogonal quadrupole
7
8 time-of-flight mass analyzers^{62, 64} allow mass analysis of intact virus capsids and large
9
10 proteins. Tandem mass analysis offers the structure information.³¹ But when particle
11
12 size becomes larger, higher energy is required to activate and dissociate those
13
14 bioparticles. During activation and dissociation of nanoparticles, trapping frequency
15
16 in an ion trap device is not able to cover a board range. Tandem in space is therefore
17
18 favored than tandem in time technique.^{125, 126} Mann *et al.* showed that dual linear ion
19
20 trap orbitrap instrument can increase sequence speed in proteomics research.¹²⁷ Dual
21
22 ion traps provide a possible solution to dissociate large ions to fragments by
23
24 combining both tandem in time and tandem in space techniques.^{58, 128} Sixthly, with the
25
26 help of AutoMass and Massign programs, analysis time of complicated ESI mass
27
28 spectra can be greatly reduced. However, automated data preprocessing is required to
29
30 minimize the effect of deformed mass spectra of heterogeneous protein complexes,
31
32 reduce the size of data and speed up the analysis time. Seventhly, pulse nature of
33
34 MALDI ion source is suitable to couple with time-of-flight mass analyzer to acquire
35
36 simple mass spectra. TOF-MS with a cryogenic detector, an active pixel detector and
37
38 a nanomembrane detector can now extend mass detection from hundred kDa to MDa.
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56 But tandem mass analysis of high mass ions in a TOF-TOF instrument and low
57
58
59
60

1
2
3
4 ionization efficiency of MALDI ion source in detecting large bioparticles (>100 kDa)
5
6
7 are still very challenging. The use of a charge detector with TOF MS and quadrupole
8
9
10 ion trap MS can help understand quantity of ions and examine the possible ionization
11
12 mechanism. Finally, mass resolution in high mass range and isotopic analysis of high
13
14 mass biomolecules¹²⁹ are still challenging for both FTICR and orbitrap mass
15
16
17
18 analyzers.
19

20 21 22 23 24 **6. Conclusions and Future Outlook** 25

26
27 Single particle quadrupole mass spectrometry approach provides accurate mass
28
29 measurement with particle sizes from 80 nm to 10 μm .⁴ But it is not suitable for high
30
31 speed analysis. Cell mass spectrometry offers destructive measurement of cells with
32
33 sizes from 700 nm to 30 μm .²⁷ It offers high speed analysis of cells. Charge detection
34
35 mass spectrometry proposed non-destructive determination of particle charges. The
36
37 signal-to-noise can be enhanced with increasing multiple paths of ions. The use of a
38
39 cryogenic detector in TOF MS can extend the detection limit up to 2 MDa.⁹⁸ With
40
41 nanomembrane detectors, IgM molecules can be detected with TOF MS with a
42
43 resolution of ~ 250 .⁴⁵ Differential mobility analysis (DMA) is now available to rapidly
44
45 characterize viruses and virus-like particles. 18 MDa viral particles with charges up to
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60 350 are explored.⁶⁴ The mass resolution has reached the instrumental limit of

1
2
3
4 quadrupole orthogonal TOF MS. Orbitrap MS might be a promising solution to
5
6
7 improve mass resolution in analyzing large bioparticles to MDa mass range.³² The
8
9
10 AutoMass, a game theory based search engine, can successfully assign the very
11
12
13 complicated tandem mass spectra of HBV capsids with m/z from 40000 to 80000.¹⁹
14
15
16 Moreover, Massign can simplify the assignment of different subunit combinations in
17
18
19 large heterogeneous systems.²⁰ Overall, mass spectrometric techniques are powerful
20
21
22 tools and continuing to provide valuable mass and structure information of large
23
24
25 biomolecules and bioparticles.

Table 1. Comparison of physical mass spectrometric techniques available for large biomolecules and bioparticles

Mass spectrometry techniques	Analytes	Analyzer/ detector	Particle Size (nm)	Particle mass (Da)	Mass resolution (m/ Δ m)	Mass accuracy	Refs.
Quadrupole ion trap mass spectrometry	Micro particles, nanodiamond, nanoparticles, bacteria/ viruses/cells	secondary electron light scattering laser induced fluorescence charge detector	<10 10-10 ³ 10-10 ² 10-10 ⁴	<10 ⁶ <10 ¹² <10 ⁵ <10 ¹⁶	10-10 ³ 10-10 ⁴ - ~10 ²	- 1% - 1%	57,69 12, 28, 53, 68, 72-75, 77-79 5, 58, 80 4, 27, 54, 82-85, 87-90
Linear ion trap mass spectrometry	protein, protein complexes, organic compounds	secondary electron, charge detector	<10 ¹	<10 ⁵	~10 ²	-	70, 130, 131
Time-of-flight (TOF) mass spectrometry	protein, protein complexes, organic compounds, polymer, nanoparticles	secondary electron, cryogenic detector, nanomembrane, charge detector	10-10 ²	<10 ⁶	10-10 ³	1%	23, 24, 45-48, 95, 96
Charge detection mass spectrometry	micro particles, nanoparticles, protein, protein complex, viruses	charge detector, linear array, recirculating trap	10-10 ⁴	<10 ¹²	10-10 ²	-	40, 55, 56, 102
Differential mobility mass Spectrometry (DMA)	nanoparticles, microparticles, bacteria/ viruses	DMA	10-10 ⁴	10 ⁹ -10 ¹²	10-10 ²	-	43, 44, 104-106
Quadrupole orthogonal time-of-flight mass spectrometry	Protein, protein complexes, virus capsids	TOF, secondary electron	10-10 ²	<10 ⁵	10-10 ³	0.1%	30, 60, 62-64, 108, 132
Orbitrap mass spectrometry	antibodies, viral cell, protein, protein Complexes	orbitrap	10-10 ²	<10 ⁶	~10 ⁴	0.001%	31, 32, 41, 109
