## Abstract

Liver is the biggest digestive gland and the essential important organ in human body. The establishment of the proteome database of the human liver would provide useful information for human liver disease treatment. To maximized protein identification and compare corresponding analysis depth, multiple technical routes were applied in proteome profiling of French liver. Five strategies, including two 2DE methods and three multi-dimensional liquid chromatography (MDLC) methods were evaluated. By using above five routes, 1627 unique proteins were finally identified. All kinds of bioinformatics analyses focused on physicochemical properties and functional classification were used to illustrate the hallmark of the protein expression profile. Furthermore, the comparison of these data with the existing liver expression profile provided by UNIGENE and UNIPROT to investigate the identification efficiency of these dataset. The different technical methods were evaluated and compared to make a model in the organ proteome profile.

Keywords: French human liver, proteomics, 2DE, MALDI-TOF-TOF-MS, ESI

## 1. Introduction

The expression profile of human liver protein could serve as a reference to motivate biomarker and drug screening for liver disease, and preventive vaccines for future application <sup>[1]</sup>. Proteomic analysis is a powerful technological tool developed in this decade and widely used in the world. The tool can help to achieve the whole set of expression profile data for any human organ. Several proteomic techniques <sup>[2-5]</sup> have been utilized to establish human organ/tissue proteome expression profile. To improve our liver proteome dataset analytically, we need definitely to develop standard operating procedures (SOPs) to establish the liver protein database, in order to understand the mystery for liver in human beings, to draw the protein atlas for the biggest human organ. The vast number of proteins presented in liver requires various method for protein mixture separation before it is introduced into mass spectrometry. <sup>[6]</sup>

A common analytical methodology relying on the separation and analysis of an intact molecule to discern information about protein function or identity was named top down strategy. <sup>[7]</sup>The most classical top down separation strategy is two dimensional electrophoresis (2DE), which has been introduced more than three decades ago. <sup>[8-11]</sup> In this conventional separation technique, the proteins are in-gel separated by two different physicochemical principles, for example, by isoelectric point (pI) and molecular weight. The gel spots belong to certain proteins were excised and in-gel digested before identification by either MALDI-TOF-TOF-MS or ESI-MSMS. <sup>[12-15]</sup> Accordingly, the approximate size and pI of identified proteins could be speculated based on the position of gel spots on 2D gel. Also, some post translational modifications can be visualized on 2D gels where “trains” of spots indicated heterogeneity due to modifications such as phosphorylation or glycosylation. 2DE have been successfully applied in

1  
2  
3  
4 profiling hepatic proteome and comparative analysis of liver disease.<sup>[16,17]</sup> However, this  
5  
6 technique has several disadvantages in detection of very acidic, basic, hydrophobic proteins and  
7  
8 low-abundant proteins in the presence of high-abundant proteins.  
9

10  
11 MDLC based bottom-up strategies, which use peptide detection to infer protein presence,  
12  
13 provide a promise alternation to 2DE, for its high-throughput separation ability of highly complex  
14  
15 samples.<sup>[18]</sup> Nowadays, MDLC coupled tandem mass spectrometric analysis has been wildly  
16  
17 applied in analyses of complete cell lysates, organisms, tissue extracts, subcellular fractions, and  
18  
19 other subproteomes.<sup>[19]</sup> MDLC strategies are usually conducted in two workflows. One using  
20  
21 protein fractionation and separation before protein digestion (Sort-then-break), the other directly  
22  
23 separate protein digests without pre-fraction of proteins, commonly referred to as 'shotgun'.<sup>[20]</sup> In  
24  
25 either route, large number of MSMS spectra can be collected in a few hours, which enables  
26  
27 detection of more low abundant peptides, although with lower protein sequence coverage  
28  
29 compared with 2DE. And the shortage of protein coverage will often lead to much more protein  
30  
31 groups to interrupt accurate identification of the protein. In conclusion, MDLC based proteome  
32  
33 profiling is complementary to 2DE based method.  
34  
35  
36  
37  
38  
39

40  
41 To maximum protein identification and compare corresponding analysis depth of different  
42  
43 technique routes for liver proteomes, five technique routes were used to analyze the protein  
44  
45 expression profile of French human liver sample. Both 2DE and MDLC based strategies coupled  
46  
47 with either MALDI-MS or ESI-MS were included. Through various bioinformatics methods, we  
48  
49 can obtain global view of the identified proteins on function and pathways involved in liver.

## 2.1 Preparation of protein samples from French human liver tissue specimens

The routine five technical routes (see Figure 1) were used in the expression profile of French human liver sample. Among them, two were mainly 2DE based technique. The other three were mainly shotgun with liquid chromatography technique. The MALDI-TOF-TOF-MS were used in first four routes. MASCOT was used as search engine for the results in all those five routes.

French human liver was provided by French Health Institute. Ten healthy donors were carefully selected according to the standard condition approved by the Institutional Review Board (IRB). The liver tissue was cut into small pieces and washed with glacial NaCl solution (0.9%) to remove blood and some possible contaminants. Then Human liver tissue is crushed with a hammer in a liquid nitrogen-cooled stainless tube for several times.

All experiments were performed in compliance with the relevant laws and institutional guidelines under Human Liver Proteome Project (HLPP). The institutional committee had approved all the experiments. The informed consent was obtained for any experimentation with human subjects.

## 2.2 The 2DE approach

### Total protein and Sequential Extraction

The human liver tissue powder is transferred to a glass homogenizer and treated with lysis buffer which contains 9M Urea, 2% Chaps, 0.14% PMSF and 0.5% DTT for total extraction. Tissue sample was homogenized in ice bath. The resulting homogenate was swirled for at least 20 min and centrifuged for 30 min. at 12,000g, 4°C. The supernatant was collected. Protein

1  
2  
3  
4 concentration of sample was measured using bovine serum albumin (BSA) as standard by the  
5  
6 Bradford assay<sup>[21]</sup>. Transfer the supernatant into several tubes after protein quantification and store  
7  
8 at  $-80^{\circ}\text{C}$  for the future use.  
9

10  
11 Proteins are treated with lysis buffer which contains 40 mM Tris for the first step. Then  
12  
13 extracts are centrifuged at 16,000g for 30 min. at  $4^{\circ}\text{C}$ . Transfer the supernatant into a clean tube.  
14  
15 Add the second lysis buffer which contains 8M Urea, 4% Chaps, and 0.5% DTT into the pellet.  
16  
17 Centrifuge the solution at 16,000g for 30 min. at  $4^{\circ}\text{C}$ . Then transfer the supernatant into a clean  
18  
19 tube. Add the third lysis buffer which contains 5M urea, 2M thiourea, 2% Chaps, 2% SB3-10 and  
20  
21 0.5% DTT into the pellet. Centrifuge the solution at 16,000g for 30 min. at  $4^{\circ}\text{C}$ . Transfer the  
22  
23 supernatant into several tubes after protein quantification and store at  $-80^{\circ}\text{C}$  for the future use.  
24  
25  
26  
27

28  
29 The lysate of total, E1, E2, and E3 was separated with 2DE. The protein concentration of  
30  
31 each part was determined by Bradford method. 2DE was performed using non-linear pH 3-10 IPG  
32  
33 strips and linear pH 4-7 IPG strips (Amersham Pharmacia, Uppsala, Sweden).1mg and 2mg  
34  
35 proteins were applied to 18cm and 24 cm strips correspondingly. Strips were rehydrated overnight  
36  
37 at room temperature. IEF was performed using an IPGphor apparatus (Amersham Pharmacia).  
38  
39 After rehydration, the strips were focused at voltages ranging from 100 V to 8000 V for a total of  
40  
41 64000V. After the first dimensional separation, IPG strips were reduced, alkylated and detergent  
42  
43 exchanged in different equilibration solution for 15 min respectively. 18cm strips were used to run  
44  
45 the electrophoresis. Second dimensional electrophoresis was performed. 24cm strips were  
46  
47 embedded on top of the precast gel (Amersham Pharmacia, Sweden) with the same method before.  
48  
49 Gels were stained with Coomassie brilliant blue staining. The stained gels were scanned using  
50  
51 ImageScanner (Amersham Pharmacia) and analyzed with ImageMaster software (Amersham  
52  
53  
54  
55  
56  
57  
58  
59  
60

Pharmacia).

### Total Protein Extraction Followed RP-HPLC Separation

Human liver tissue is treated as mentioned. Then 0.2 g total protein is dissolved with lysis buffer which contains 8M Urea, 0.14% PMSF and 0.5% DTT for total protein. Use reversed phase column (300 Å, 5µ, 4.6x 250mm) with binary gradient ( A: 0.1%TFA in water; B: 0.1%TFA in ACN) to separate the whole protein into 10 fractions. After the salt peak, collect the fraction every 12 minutes with flow rate 0.8 ml/min. Collect the fractions with the same condition five times. Quantify the protein concentration and store at -80°C for the future use.

Liquid chromatography separation and fractions collection were performed by using a Shimadzu LC-2010A system with FRC-10A system and SCL-10A VP system. Protein sample was loaded onto the C18 reversed-phase column (250x4.6mm, 5µm, 300Å, Hypersil, elite HPLC, China). 0.1%TFA was used as buffer A, 100% acetonitrile + 0.1 % TFA were used as buffer B. Elution was conditioned as linear gradient and listed as following: 10 min of 100% buffer A, 20 min linear gradient from 0% to 30% buffer B, then 80 min linear gradient from 30% to 90% buffer B, 5 min of 90% buffer B and 2 min back to 0% buffer B. All fractions were collected every 3 minutes automatically. The chromatograms were monitored at 215 nm and all fractions were lyophilized and dissolved in 2DE buffer.

Pooled fractions were re-dissolved in a rehydration buffer as usual. Focusing was carried out in 18cm strip with a pH range of 3-10 (NL) at 20°C as before. Rehydration procedure and the procedure transferred to the second dimension were the same as before.

## 2.3 In-gel digestion

### Coomassie blue stained spots

Excised gel pieces were placed in 96-well plate and destained with 100  $\mu$ L 50% ACN / 50 mM ammonium hydrogen carbonate for two times (15 min each time). After removal of solution, 100  $\mu$ L of 100% ACN was added and remained for 10 min. Then, ACN was discarded and the gel pieces were incubated at 37°C for 10 min. in order to remove the excessive ACN. 3  $\mu$ L 12.5 ng/ $\mu$ L (sequence grade, fresh diluted in 25 mM  $\text{NH}_4\text{HCO}_3$ ; Promega, USA) trypsin solution was added to each of the dry gel pieces and incubated overnight at 37°C. Peptides were extracted by adding 60  $\mu$ L of 0.1% TFA, 50% ACN to each well and remaining for 30 min. The supernatants were removed to a fresh 96-well plate and the peptide extraction procedure was repeated. Then, combined the two extracts and dried the solution by using high purity nitrogen. 5 mg/ml matrix (50% ACN/0.1% TFA) was added to the bottom of the dried 96-well plate and gently pipetted up and down several times to dissolve the extracted peptides. Matrix and sample were spotted onto a stainless steel MALDI target plate. The dried deposited fractions were analyzed by using a 4700 Proteomics Analyzer MALDI-TOF-TOF-MS (Applied Biosystems).

### Silver stained spots

Excised gel pieces were placed in a 96-well plate and were de-stained with 15  $\mu$ L of fresh solution containing 15 mM  $\text{K}_3\text{Fe}(\text{CN})_6$  and 50 mM  $\text{Na}_2\text{S}_2\text{O}_3$  (v/v 1:1) for 20 min. Wash gel pieces twice with water by waiting for another 20 min. After removal of solution, 80  $\mu$ L of 100% ACN was added and remained for 10 min. Then, ACN was discarded and the gel pieces were incubated

1  
2  
3  
4 at 37°C for 10min. in order to remove the excessive ACN. All the consequent procedures were  
5  
6 same as coomassie blue stained spots.  
7  
8  
9

## 10 11 12 **2.4 Shotgun route** 13

14  
15  
16 The tissue specimens was suspended in the protein extraction buffer (8 M urea, 20 mM  
17  
18 Tris-HCl, pH 8.5, 1 mM DTT, phosphatase inhibitors: 1 mM PMSF, 0.2 mM Na<sub>2</sub>VO<sub>3</sub> and 1 mM  
19  
20 NaF; and Protease Inhibitor Cocktail dissolved in the lysis buffer according to usage specification).  
21  
22 Lysis was performed by homogenization on ice and aided by vortex of 30 min. The lysate was  
23  
24 centrifuged at 26, 000g for 90 min at 40°C. The supernatant was collected as the global protein  
25  
26 sample. Protein concentration was measured by a Bio-Rad assay using BSA as standard. The  
27  
28 proteins were reduced with 10 mM DTT at 37°C for 1 h and then alkylated with 25 mM  
29  
30 iodoacetamide for an additional 30 min at room temperature in the dark. After diluting the urea to  
31  
32 2 M with 25 mM ammonium bicarbonate (pH 8.5), a tryptic digestion was performed on one  
33  
34 portion of the global protein sample overnight at 37°C.  
35  
36  
37  
38  
39  
40  
41

## 42 **Protein and peptide pre-fractionation by SEC** 43

44  
45  
46 Size exclusion chromatography (SEC) was performed at the intact protein level as follows:  
47  
48 1.0 mg protein was injected onto a Shodex PROTEIN KW-803, 8 mm x 300 mm column (Tokyo,  
49  
50 Japan) and the SEC separation was performed with an isocratic gradient produced by a Shimadzu  
51  
52 LC-2010A (Kyoto, Japan) system at a rate of 0.3 mL/min consisting of 2 M urea, 25 mM  
53  
54 NH<sub>4</sub>HCO<sub>3</sub>, pH 8.5, for the mobile phase. Parallel SEC separations of the same protein sample  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 were performed. All eluted fractions were lyophilized. Then sequencing grade trypsin was added  
5  
6 at a mass ratio of 1:50 and incubated at 37°C for 16 h. The peptide pre-fractionation was  
7  
8 performed in a similar way for peptide separation, the mobile phase was changed into 25 mM  
9  
10  $\text{NH}_4\text{HCO}_3$  (pH 8.5) and without any removal of urea or post-column digestion.  
11  
12

### 13 14 15 **Strong cation-exchange chromatography-RPLC separation**

16  
17  
18 LC experiments were performed with an Ulti-Mate™ nano scale LC system combined with a  
19  
20 FAMOS microautosampler and a Switchos valves from LC Packings (Amsterdam, The  
21  
22 Netherlands). Strong cation-exchange chromatography SCX-RPLC systems were used to separate  
23  
24 the samples for obtaining more proteins.  
25  
26  
27

## 28 29 30 **2.5 Mass spectrometry**

### 31 32 33 **2DE-MALDI-TOF-TOF-MS**

34  
35  
36  
37 Mass spectra were obtained in a mass range of 500-3200 Dalton by using laser (337 nm, 200  
38  
39 Hz) as ionization source. The instrument was used in reflector-positive mode with an acceleration  
40  
41 voltage of 15 kV. Trypsin digested peptides of horse myoglobin was used as external mass  
42  
43 standard to calibrate the instrument, and then default calibration was applied on the sample  
44  
45 peptides. The TOF-TOF mass spectra were acquired by the Data Dependent Acquisition method  
46  
47 with 6 strongest precursor ions selected automatically from one MS scan for MSMS analysis.  
48  
49  
50 Protein identification using combined raw data (PMF+ MS-MS) was performed with GPS  
51  
52 software (Applied Biosystems; containing MASCOT search engine) against the non-redundant IPI  
53  
54 human (version 3.25) protein sequence database. The mass tolerance was set as 100 ppm, and  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 MSMS tolerance was 0.6 Da for automatic data analysis. For partial data, we use different  
5  
6 criterion to run MS.  
7  
8

### 9 10 **Online 2DLC-MSMS**

11  
12  
13 The procedure of separation was similar to the established comprehensive nano  
14  
15 SCX-RPLC-MSMS system<sup>[11]</sup>. The sample loading and column equilibrium solvent of the SCX  
16  
17 dimension: 95% water 15% ACN 10.1% FA with flow rate 5 mL/min. 20mM ammonium acetate  
18  
19 salt solutions of 0, 5, 10, 20, 30, 40, 60, 80, 150, 400, 600, 800, 1000, 1500 and 2000 mM was  
20  
21 injected into the SCX column for a step gradient elution of peptides. A cartridge type trap column  
22  
23 was used to pre-concentrate and desalt each peptides fraction eluted from SCX column prior to  
24  
25 nano-RPLC separation. SCX fractions were separated on a nano-flow reversed phase column. A  
26  
27 continuous gradient elution was performed with solvent A (0.1% FA , 5% ACN, 95% water, v/v)  
28  
29 and B (0.1% FA , 95% ACN, 5% water, v/v) at a flow rate of 250 nL/min. Quadrupole orthogonal  
30  
31 TOF mass spectrometers were used to acquire ESI/MSMS spectra (QSTAR XL). Protein  
32  
33 identification using combined raw data (PMF+ MS-MS) was performed with GPS software  
34  
35 (Applied Biosystems; containing MASCOT search engine) against the non-redundant IPI human  
36  
37 (version 3.25) protein sequence database. The mass tolerance was same as before. For partial data,  
38  
39 we use different criterion to run MS. PMF was run at first. When the PMF score was greater than  
40  
41 100, this score would be taken as confidential result and then MSMS procedure was skipped.  
42  
43  
44 When the PMF score was smaller than 100, then six highest peaks among the PMF were picked  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60 and MSMS was run to determine if the score was above the confidential level.

## 2.6 Bioinformatics analysis

### Analysis of chromosomal localization

The localization information of protein in chromosomes was provided by the IPI database. The information of the chromosome length was provided by Bioconductor (<http://www.bioconductor.org>). Chromosome plot was completed by the software which was provided by Integrative Genomics Viewer (IGV).<sup>[22]</sup>

### Gene Ontology analysis

Gene Ontology item for each IPI protein was retrieved from GOA Database (Gene Ontology Annotation, <http://www.ebi.ac.uk/GOA>), and all the GO items were then slimed to parent GO items in order to summarize the protein number in the specific functional class. All the work was fulfilled by a home-made MATLAB program.

### The reference database for liver

The cluster data collected from non-redundant clusters of genetic sources were provided by NCBI the United States UNIGENE (<http://www.ncbi.nlm.nih.gov/unigene>) database. UniGene Cluster includes a single gene sequences and related information represents for each individual, such as gene expression of tissue types, and map location information. The expression information of tissue types provided from UNIGENE can be used as the largest information source of liver transcriptome. The Knowledgebase provided from UNIPROT (<http://www.uniprot.org>) was by far the most important protein sequence, function, classification, cross-references and other

1  
2  
3  
4 information access center. The tissue expression of protein-specific information was also provided  
5  
6 by UNIPROT. This can be used as a liver-background proteomics dataset.  
7  
8  
9

### 10 11 12 **3. Results and Discussion** 13

14  
15 The comprehensive proteomics is necessary and solid basis for panoramic display of cellular  
16  
17 proteome and exploratory research of internal linkage of proteins. This can give us a global  
18  
19 overview and can establish the reference dataset for disease treatment.  
20  
21

22  
23 The routine five technical routes were used in the expression profile of French human liver  
24  
25 project. Among them, two were 2DE based methods, the other three were mainly shotgun with  
26  
27 liquid chromatography technique. The MALDI-TOF-TOF-MS were used in first four routes.  
28  
29 MASCOT was used as search engine for the results in all those five routes.  
30  
31

32  
33 The pooled fractions eluted from the column were subjected to 2DE by using IEF strip pH 3  
34  
35 -10 (fraction 3 and fraction 10) and pH 4 -7 (the rest of 6 fractions). Due to the enrichment effect,  
36  
37 the protein patterns of 2DE were nearly as complex as the protein pattern of the un-fractionated  
38  
39 sample. This was confirmed by the observation of the spot numbers of 2DE fraction 3-10.  
40  
41

42  
43 In this route, ABI 4700 MAIDI-TOF-TOF MS was selected as the instrument for protein  
44  
45 identification. Total 14629 spots picked from 2D-Gel were put on the 81 MALDI plates for  
46  
47 sequential protein identification. For the research of former scientists employing the  
48  
49 strip-2DE-technique, there was more than one protein in most spots of 2D-Gel for tissue  
50  
51 expression profile or standard sample. In common situation, one spot on the gel corresponding to  
52  
53 all identified proteins above the threshold value given by MASCOT, is defined as Rank\_All, and  
54  
55 the top score one is defined as Rank\_1. However Rank\_1 was chosen as protein candidate in most  
56  
57  
58  
59  
60

1  
2  
3  
4 2DE references. In order to review the confidential level of Rank\_1 and Rank\_All, a reversed  
5  
6 database was used to evaluate the above two strategies.

8  
9

## 10 11 12 **Proteome Profiling of French Liver** 13

14  
15 The comprehensive proteomics is necessary and solid basis for panoramic display of cellular  
16  
17 proteome and exploratory research of internal linkage of proteins. This can give us a global  
18  
19 overview and can establish the reference dataset for disease treatment. Five technique routes were  
20  
21 applied in proteome profile of French liver. As show in figure 1, route 1 and 2 were based on 2DE  
22  
23 separation, excepted that route 2 incorporates 1D RPLC separation before to 2DE. The other three  
24  
25 shotgun strategies take advantage of orthorgic SCX-RPLC separation. To maximum the  
26  
27 identification, additional SEC separation was set before or after trypsin digestion in route 4 and 5.  
28  
29 The MALDI-TOF-TOF-MS were used in first four routes, while ESI-Q-TOF was applied in route  
30  
31 5. MASCOT was used as search engine for all five routes.  
32

## 45 **Analysis of 2DE based strategy** 46

47  
48 In the identification of 2DE proteins, the precursor ion score distributions of all the target and  
49  
50 decoy results from one gel spot (Rank\_All) were almost the same. While for Rank\_1 results  
51  
52 (highest rank of protein score), there were significant differences in protein score, ion score,  
53  
54 MSMS number between target and decoy results (Suppl. Fig 1). Therefore, it is reasonable to set  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 the threshold of confident identification accordingly to Rank\_1 results. A total of 132 MALDI  
5  
6 plates together with 14629 spots were analyzed by MS in route 1. Since not all the spots on the  
7  
8 MALDI plate have MSMS information, we divided the MALDI peaklists into two groups, with or  
9  
10 without MSMS spectra for individual quality control, and set both 95% confidence. 4728 out of  
11  
12 5185 spots (91%) with MSMS spectra passed corresponding threshold, which belonged to 609  
13  
14 non-redundant proteins. While only 28% of PMF spectra were successfully identified, resulting in  
15  
16 393 non-redundant proteins (Suppl. Fig 2). So we can conclude that MSMS data play important  
17  
18 role for improving the protein score and protein identification. Combining the two groups, 724  
19  
20 proteins were successfully identified from 14629 gel spots.  
21  
22  
23  
24  
25  
26

27  
28 Although the 2DE routes provide high sequence coverage in protein identification, the  
29  
30 proteome profiling efficiency was restricted by the high redundant protein identifications, since a  
31  
32 single protein can migrate to multiple spots on 2D gels (20.21 spots per protein in route 1). To  
33  
34 expand the dynamic range and reduce the redundancy, RPLC was used for protein fraction before  
35  
36 2DE in the second route. In the RPLC-2DE routes, 3955 spots spotting on 39 MALDI plates were  
37  
38 analyzed, and 315 non-redundant proteins passed correspondent threshold defined in route 1  
39  
40 (Suppl. Fig 3, 4). The redundancy reduced nearly 50% after RPLC pre-fraction, from 20.21 to  
41  
42 12.56 spots per protein. Although the sequence coverage of protein as well as successful  
43  
44 identification ratio of MALDI spots were totally lower than the route 1, route 2 still can greatly  
45  
46 increase the identification efficiency by means of less redundancy. The detail comparison  
47  
48 information of route 1 and route 2 show in table 1.  
49  
50  
51  
52  
53

## Analysis of Multidimensional LC based strategy

In the LC-MALDI strategy of route 3 and 4, the number of MSMS ions shows major effect to improve the protein score. The peak-lists of each fraction were merged together for database searching. The emPAI value dependent on the number of MSMS ions was used for quantification. Altogether, 299 non-redundant proteins were identified in the 21 fraction of route 3 (SCX-RPLC-4700). Unique peptide/spectrum was 0.85, and there are 4.2 peptides for each protein. The route 4 and 5 were both using 3DLC for sample fraction, 996 and 247 non-redundant proteins were identified by these two routes respectively, and 81.9% of route 3 identified proteins were detected in route 4 and 5. An extra of 767 and 138 proteins were identified by route 4 and 5 respectively. From the above results, we can conclude that 3DLC route can mostly cover 2DLC route and more proteins can be identified by 3DLC. Comparing with route 3 and 4, the 94 fraction of route 4 was analyzed by ESI coupled MS analyzer QSTAR XL. The number of MSMS ions has no significant correlation with protein score. And the value of unique peptide per spectrum is lower than that of in the LC MALDI route. Which means the identified MS graph contribution of unique peptides is relative lower. However, the number of identified protein was more than LC MALDI route. The detail comparison information of route 3, route 4 and route 5 show in table 1.

Table 2. Protein identification efficiency between route 3, route 4 and route 5.

## Overlap of the 5 technique routes

There are total 1627 non-redundant proteins correspondent to 1030 genes in total five technical routes. 1075 proteins (66.1%) were identified by only one technical route. 552 (33.9%)

1  
2  
3  
4 proteins were identified by both two technical routes or above (Figure 2A). There were 724  
5  
6 non-redundant proteins identified by route 1, while 315 non-redundant proteins identified by route  
7  
8 2, and 211 proteins were identified by both technical routes. Although compared with the first  
9  
10 route, there are  $211/724 = 29\%$  similarity between first and second routes. In the second route,  
11  
12  $104 / (104 + 211) = 33.0\%$  new proteins were provided compared to the first route  $27\%$   
13  
14  $(3955/14629)$ . This means RPLC pre-fraction before 2DE is a good complementary method to  
15  
16 the pure 2DE technical route (Figure 2C, a). There are only 93 proteins overlapped in the three  
17  
18 shotgun routes which means the orthogonality of the experiments (Figure 2C, b). There are 828  
19  
20 proteins identified by top down route and 1154 proteins identified by shotgun routes. There are  
21  
22 355 proteins were identified by both routes, less than 50% overlap. This means these two  
23  
24 experimental routes have strong complementary property with each other. (Figure 2C, c). The  
25  
26 identified peptide number corresponding to each technique route are showed in Figure 2A, 2D.  
27  
28 For quantification, the similarity of the curve of protein identification for both two top down  
29  
30 routes was very high, and so did three shotgun routes. But the similarity between top down and  
31  
32 shotgun was not so high. (Figure 2B).

Figure 2. Protein number comparison of the 5 technique routes.

### Comparison of Physical and chemical property

The physical and chemical properties of identified peptides (redundant peptide) of each technical route were analyzed. The identified proteins are biased to the high molecular zone, low iso-electric points and high hydrophobicity (in the right side of next figure). Little difference of physical and chemical properties for identified proteins was observed between 2DE based routes and shotgun routes. While shotgun routes detected more basic proteins compared with 2DE based routes. Accordingly, the distributions of all identified proteins in isoelectric points shows significant different between the two routes. There were more hydrophilic high abundant proteins identified in the cytoplasm in the 2DE based routes. In the physics, chemical property analysis of each technique route, the results showed that more long peptide with high molecular weight in shotgun routes was identified. And there were more proteins identified with higher and wider iso-electric points in Route 5 due to the large numbers of identified peptides. There were more quantity of  $\alpha$ -helix,  $\beta$ -sheet and  $\beta$ -turn in proteins identified in shotgun routes than in 2DE based routes. The contents of amino acid G, Q, R, S were relatively higher in the identified peptides in shotgun routes. Amino acid N was relatively more in the route 5. Amino acid R was relatively less in route 1. In conclusion, top down and shotgun route complement with each other for protein identification (Suppl. Fig 5).

Figure 3. The physical and chemical distribution of the identified proteins.

## Over 90% identified proteins were liver proteins

To compare the coverage of different technical routes for the expressed protein in liver, a cross linked database for liver expressed proteins was constructed. For proteomics, UNIPROT database was used. This database only collects proteins of abundant annotation information validated by experiments. 1986 proteins expressed in liver were screened out according to the keyword Tissue\_Specificity. In transcriptome, NCBI UNIGENE database was used. UNIGENE is a transcript expression library which is assembled EST into mRNA by sequence technique. Liver expressed mRNA can be screened out within this database according to keyword “Restriction Expression” . There were 19983 UNIGENE correspondent to 40170 proteins for liver expressed in UNIGENE (version 208). Combining UNIGENE and UNIPROT, liver protein database with 40913 proteins was established. The number of identified proteins in the fourth technical route is most. 84% of proteins are proved to be expressed in the liver. All other technical routes are proved above 90%. The proteins expressed in liver in UNIPROT by each technical route were only in the range of 12% to 17%. (Figure 4)

Figure 4. Comparison of identified proteins with known liver expressed proteins.

## Functional annotation of liver proteins

There is not too much difference for the subcellular location in all five technical routes. Among them, the most number of identified proteins is cytoplasm, then membrane or mitochondrion, with lysosome at least. The subcellular location is similar between two 2DE based routes, so did the first two routes within shotgun. The distribution of Biological Process in all five technical routes is similar. The number of identified proteins is higher in Transport and

1  
2  
3  
4 metabolism. On the other hand, cell cycle, apoptosis, cell adhesion and cell motility which are  
5  
6 related to the cell state are least. The tissue sample is come from adult liver, so the expression rate  
7  
8 of this kind of proteins would be low (Figure 5).  
9

10  
11  
12  
13  
14 Figure 5. Functional comparison of identified proteins in 5 technique routes.  
15

16  
17 24 human chromosomes were connected from begin to end according to their base position to  
18  
19 composite the whole human genome. The width of chromosome position and length are directly  
20  
21 proportional. When the identified proteins of all five technical routes were mapped to the genome,  
22  
23 the bar graph shape of identified proteins was similar between two 2DE based routes, so did three  
24  
25 routes within shotgun. Especially, the pattern of most abundant proteins on chromosomes in route  
26  
27 3 and route 4 are almost the same. Chromosome 1 has the most identified proteins in all technical  
28  
29 routes, and then chromosome 12, 6 and 2 (Figure 6).  
30  
31  
32

33  
34 Figure 6. Chromosome analysis of identified proteins in 5 technique routes.  
35  
36  
37  
38

39  
40 Generally, it was considered that the proteomics techniques were difficult for the  
41  
42 identification of low abundant proteins due to some technical deficiencies. Therefore the coverage  
43  
44 derived from proteome is always lower than transcriptome. In addition to technical reasons, it  
45  
46 could also be caused by some biological reasons. In organisms, the expression occurred highly at  
47  
48 the transcription level for many genes. However, the corresponding expressed protein abundance  
49  
50 was relatively low on account of the intermediate degrading process. So this had some  
51  
52 disadvantages for the identification at the protein level. On the contrast, this might also be owing  
53  
54 to the slow degrading process and the high efficient translation rate, which could be easily  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 identified at the protein level.  
5

6 Therefore, to identify the disease-associated proteins is the key to study mechanisms of liver  
7  
8 cancer. Since most important proteins which attend the signal transduction and biological process  
9  
10 are low abundance, we need to have a very powerful technical method to identify those important  
11  
12 low abundant proteins besides using classical method.  
13  
14

15  
16 It is well known that about a half million human proteins are encoded by more than 20,000  
17  
18 genes. It is proteins that execute the biological processes directly. Thus the state of an organism is  
19  
20 essentially reflected in its proteome rather than genome. Liver cancer is one of the most fatal  
21  
22 diseases worldwide and the mortality rate has been raised up to the second among malignancies in  
23  
24 China. Different technical methods were used and compared to choose the best alternative one for  
25  
26 different purpose. Our strategy can provide the objective technical method for the organ proteome.  
27  
28  
29  
30  
31  
32  
33  
34

#### 35 **4. Concluding Remarks**

36  
37 By using five different routes with different experimental strategies on whole protein  
38  
39 expression profile in French human liver tissue, 1627 unique proteins correspondent to 1030 genes  
40  
41 were finally identified, and all the identified proteins were analyzed with various bioinformatics  
42  
43 method to observe the general function of French liver. The standard operating procedures (SOPs)  
44  
45 had been tried to be set up to yield good model references for the others. The establishment of the  
46  
47 proteome database of the French human liver will be a piece of very useful information for human  
48  
49 liver disease understanding and treatment.
