**A silver catalysed synthesis of 6-acyl phenanthridines by oxidative radical decarboxylation/cyclization of  $\alpha$ -oxocarboxylates and isocyanides was developed. This reaction provided a novel method to realize C1 insertion via radical process and various functional groups were well-tolerated.**

Radical chemistry has ushered in a new era in the development of chemistry and it has become an important and effective tool in organic synthesis in the past decades<sup>1</sup>. Among a wide variety of radical reactions, insertion reaction is one of the most useful reactions in synthetic chemistry because the carbon chain of product can be extended<sup>2</sup>. In general, there are two pathways of insertion reactions for a carbon radical centre (scheme 1(1)). The first is C2 insertion (Path A): the carbon radical reacts with an acceptor to form a new  $\beta$  carbon radical centre thus leading to increase two atoms in chain propagation. In C2 insertion reactions, the acceptors mainly contain C-C multiple bonds like alkenes and alkynes, C-N double bonds like imines and C-O double bonds such as aldehydes, ketones and other carbonyl compounds. The other pathway is C1 insertion (Path B): the carbon radical is inserted by an acceptor to increase one carbon atom in chain propagation and a new  $\alpha$  carbon radical centre is formed. Among various C1 insertion reactions, CO is one of the most common acceptor which reacts with a radical to generate a new acyl radical by carbonylation<sup>3</sup>. Similar to CO, isocyanides can also act as radical acceptors to form imidoyl radicals, followed by bimolecular addition or cyclization<sup>4</sup>. However, only few works have been focus on this field and limited radical precursors were developed such as halides<sup>5</sup>, boronic acids<sup>6</sup>, CF<sub>3</sub> reagents<sup>7</sup>, aldehydes and diphenylphosphine oxide<sup>8</sup>. Therefore, it is still necessary to develop more radical precursors to realize isocyanides insertion via radical process.

Transition metal catalysed decarboxylation of carboxylic acids has become an important protocol to form C-C and C-Hetero bond in recent years<sup>9</sup>. For example, radical decarboxylation of  $\alpha$ -oxocarboxylic acids can also act as a powerful and complementary

synthetic method to provide acyl radical, which presumably shows higher activity and promising potential in a broad arrange acylating reaction than traditional Friedel-Crafts acylation. Herein, we envisioned to realize this radical decarboxylation by utilizing  $\alpha$ -oxocarboxylic acids as the acyl radical resources to construct 6-acyl phenanthridines, which demonstrate a plurality of biological and photochemical activities and show great potential in medical chemistry and material applications<sup>10</sup>. To the best of our knowledge, this is the first example for realizing isocyanides insertion by using acyl radical via the oxidative radical decarboxylation (scheme 1(2)).

**Scheme 1.** (1) Two pathways of insertions: C2 insertion (path A) and C1 insertion (path B); (2) Oxidative radical decarboxylation/cyclization of  $\alpha$ -oxocarboxylates and isocyanides.

Initially, we started to evaluate the reaction parameters by employing 2-isocyanobiphenyl (**1a**) and potassium oxophenylacetate (**2a**) as model substrates. To our delight, the use of 10 mol% Ag<sub>2</sub>CO<sub>3</sub> as the catalyst and K<sub>2</sub>S<sub>2</sub>O<sub>8</sub> as the oxidant in DMF at 100 °C could give the corresponding 6-benzoyl phenanthridine (**3a**) in 47% yield (Table 1, entry 1).

**Table 1.** Optimization of conditions for the reaction of 2-isocyanobiphenyl (**1a**) and potassium oxophenylacetate (**2a**)<sup>a</sup>

Entry	Catalyst	Oxidant	Solvent	Yield <sup>b</sup> (%)
1	Ag <sub>2</sub> CO <sub>3</sub>	K <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMF	47
2	Ag <sub>2</sub> O	K <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMF	42
3	AgOAc	K <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMF	41
4	AgNO <sub>3</sub>	K <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMF	39
5	-	K <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMF	6
6	Ag <sub>2</sub> CO <sub>3</sub>	K <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMSO	69
7 <sup>c</sup>	Ag <sub>2</sub> CO <sub>3</sub>	Na <sub>2</sub> S <sub>2</sub> O <sub>8</sub>	DMSO	75(71)

9	Ag <sub>2</sub> CO <sub>3</sub>	O <sub>2</sub>	DMSO	Trace

<sup>a</sup> Reaction conditions: **1a** (0.375 mmol), **2a** (0.25 mmol), catalyst (10 mol%), oxidant (0.5 mmol), solvent (1.5 mL), 100 °C, N<sub>2</sub>, 6h. <sup>b</sup> Yield determined by GC analysis. <sup>c</sup> Yield in the parentheses was isolated yield.

Then we tried other silver salts, such as Ag<sub>2</sub>O, AgOAc and AgNO<sub>3</sub>, slightly lower yields was obtained (entries 2-4). It is noteworthy that Ag salts might play a critical role from the blank experiment (entry 5). When the solvent was changed to DMSO, the yield was up to 69%. The reaction also proceeded in various oxidants such as Na<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub>O<sub>8</sub> and dioxygen (1 atm) (entries 7-9), and Na<sub>2</sub>S<sub>2</sub>O<sub>8</sub> gave the best result to promote this reaction respectively.

With the optimal conditions established, various  $\alpha$ -oxocarboxylates **2** were tested to react with 2-isocyanobiaryls **1** to form the corresponding 6-acyl phenanthridines products **3** (table 2). This reaction was successfully amenable to a wide range of  $\alpha$ -oxocarboxylates, and moderate to good yields were achieved with substrates bearing various functional groups such as Me (**3b** and **3c**), OMe (**3d** and **3e**) and F (**3f**). In addition, heterocyclic  $\alpha$ -oxocarboxylates like thiophene was found to be favoured under this catalytic system to afford the corresponding products (**3g**). It is noteworthy that aliphatic  $\alpha$ -oxocarboxylates were compatible in this reaction as well and gave moderate yields (**3h**). Furthermore, the reactivity of different isocyanides were also investigated. Isocyanides bearing the both electron-rich (**3i** to **3n**) and deficient groups (**3r**) underwent this oxidative radical decarboxylation/cyclization process smoothly to afford the desired products in moderate to good yields. In addition, this transformation also showed satisfactory tolerance with halogen groups (**3o** to **3q**) which provided useful handles for further transformations through traditional cross coupling reactions.

In order to gather insights into this novel oxidative decarboxylation/cyclization, radical scavengers, such as TEMPO and BHT, were employed in the reaction (Table 3). As a result, the reactions were completely shut down, which could indicate that this transformation involved radical intermediates.

Moreover, although it is widely proposed that Ag(I) could be easily oxidized to Ag(II) in the presence of persulfates as the

oxidants according to relative reports<sup>11</sup>, recently Maiti's group has demonstrated a novel Ag(0)-Ag(I) catalytic circle in the presence of persulfates from XPS<sup>12</sup>. This result intrigued us to investigate the plausible oxidation state of Ag species in our reaction. Therefore, we tried to use electron paramagnetic resonance (EPR) to study this oxidative process. As shown in Figure 1(a), no EPR signal was observed when AgOTf was tested alone in DMSO, 80 °C, N<sub>2</sub> for 2 hours<sup>13</sup>. However, when the mixture of AgOTf and Na<sub>2</sub>S<sub>2</sub>O<sub>8</sub> under the same condition, a strong EPR signal could be detected (Figure 1(b)). According to relative literatures, we may ascribe this obvious signal to Ag(II) species<sup>14</sup>. Therefore, this oxidative radical decarboxylation referred a Ag(I)-Ag(II) catalytic circle via a single electron transfer (SET) process.

**Fig 1.** Evidence of Ag(II) species in EPR spectra.

According to the previous reports and above results<sup>3, 11, 15</sup>, a proposed mechanism was described in Scheme 2. In the presence of  $\text{Ag}_2\text{CO}_3$  and  $\text{Na}_2\text{S}_2\text{O}_8$ ,  $\alpha$ -oxocarboxylates **I** experienced an oxidative radical decarboxylative process to generate the benzoyl radical **II**. The addition of the benzoyl radical to the isocyanide **III** generated the imidoyl radical **IV**, which next cyclized to the arene to form cyclohexadienyl radical **V**. Subsequently, a single electron transfer process happened between the cyclohexadienyl radical **V** and Ag(II) and finally give the desired product 6-acyl phenanthridine **VI**.

**Scheme 2.** Proposed mechanism.

## Conclusions

In summary, we have demonstrated a novel approach for the silver catalyzed synthesis of 6-acyl phenanthridines by oxidative radical decarboxylation/cyclization of  $\alpha$ -oxocarboxylates and isocyanides. This reaction provides a complementary method to realize C1 insertion via radical process. In addition, this method presented a variety of functional groups tolerance and showed promising potential in biological activities and pharmaceutical applications. The EPR experiments provided information that this reaction experienced a Ag(I)-Ag(II) catalytic circle.
