

Analytical Methods

Accepted Manuscript

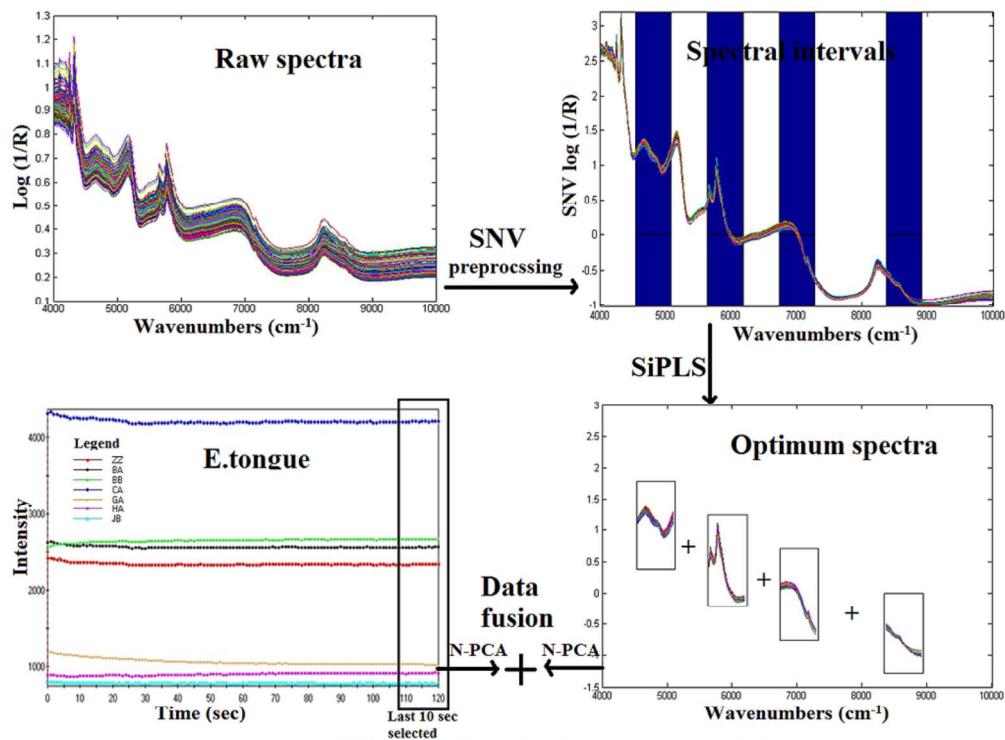

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

20
21 9 **ABSTRACT**

22
23
24 10 Total polyphenols content (TPC) is an important phytochemicals in cocoa beans due to its
25
26 11 numerous health benefits. This work attempted to measure the total polyphenols content in cocoa
27
28 12 beans by using a novel approach of integrating near infrared spectroscopy (NIRS) and Electronic
29
30 13 tongue (ET). 110 samples of cocoa beans with different polyphenols content were used for data
31
32 14 acquisition by NIRS and ET respectively. The optimum individual characteristic variables were
33
34 15 extracted from technique and scaled by normalization in principal component analysis (PCA).
35
36 16 Support vector machine regression (SVMR) was used to construct the model. The performance
37
38 17 of the final model was evaluated according to: correlation coefficient (R_{pre}), root mean square
39
40 18 error of prediction (RMSEP) and bias in the prediction set. Compared with a single technique
41
42 19 (NIRS or ET), the data fusion was superior for the determination of TPC in cocoa beans. The
43
44 20 optimal data fusion model was achieved with: $R_{pre}=0.982$, $RMSEP=0.900$ g/g and $bias=0.013$ in
45
46 21 the prediction set. The overall results demonstrate that integrating NIRS and ET is possible and
47
48 22 could improve the prediction of TPC in cocoa beans.

8 25 1. INTRODUCTION

9
10 26 Cocoa bean products are increasingly becoming a popular beverage worldwide due to its
11
12 27 numerous health benefits or medicinal properties. Recent studies have shown that the
13
14 28 consumption of cocoa bean products can enhances the general well being of humans due to the
15
16 29 present of polyphenols. Cocoa bean contains more polyphenols per serving than tea and coffee ¹.
17
18 30 These phytochemicals have important role in preventing coronary artery disease, cancers and it is
19
20 31 a myocardial stimulant, diuretic, coronary dilator and muscle relaxant²⁻⁴. Also, polyphenols
21
22 32 compounds in cocoa beans are mainly responsible for the characteristic; taste, flavour and
23
24 33 astringency of the fermented cocoa beans. It is therefore very important to determine the total
25
26 34 polyphenols in cocoa beans and over the years, the methods employed for the determination of
27
28 35 total polyphenols content include: colorimetric ⁵, thin-layer chromatography ⁶ and high-
29
30 36 performance liquid chromatography ⁷. However, these reputable analytical methods are
31
32 37 expensive, time consuming, destructive, involves chemical usage, and very tedious.
33
34
35
36
37
38

39 38 To overcome these drawbacks, near infrared spectroscopy (NIRS) and electronic tongue
40
41 39 (ET) has emerged as a novel tool for qualitative and quantitative measurements. These methods
42
43 40 are; fast, accurate, reliable and non-destructive with no chemical usage .Together with recent
44
45 41 advancement in computers and chemometrics, NIRS and ET have been used in various fields
46
47 42 such as agricultural, nutritional, medicinal and petrochemical ⁸ and process monitoring, freshness
48
49 43 evaluation, authentic assessment, foodstuffs recognition and quality analysis ⁹ respectively.
50
51 44 Specifically in previous studies, NIRS has been used to determine various phytochemicals in
52
53 45 cocoa beans such as protein, fat, carbohydrate, nitrogen and moisture content¹⁰⁻¹². Furthermore,
54
55
56
57
58
59
60

1
2
3 46 Alvarez and co-workers¹³ determined fats, caffeine, theobromine and epicatechin in
4
5 47 unfermented and sun dried criollo cocoa and Whitacre and others¹⁴ predicted the content of
6
7 48 cocoa procyanidins. While, ET has been used by other research such as: Teye, et al¹⁵ for
8
9 49 discrimination of cocoa beans according to geographical origin, Chen, et al.¹⁶ for identification
10
11 50 of green tea grade level. Also, Chen, et al.¹⁷ used taste sensor technique to determine caffeine
12
13 51 and main catechin content in green tea. Other studies are analysis of goat milk adulterated with
14
15 52 bovine milk¹⁸, detection of sugars and acids in tomatoes¹⁹.

19
20 53 Although the combination of NIRS and ET is most likely to increase the performance of
21
22 54 measurements, articles in this area are lacking. Also, upon a thorough literature search, little
23
24 55 information is available on the use either NIRS or ET for rapid analysis of total polyphenols
25
26 56 contents in cocoa bean. More so, the use of NIRS for the prediction of cocoa procyanidins,
27
28 57 theobromine, and epicatechin was done with partial least squares (PLS) regression and modified
29
30 58 PLS model. The modified PLS was used to manually select different spectral band and this might
31
32 59 weaken the performance of the calibration model without prior experienced in the knowledge
33
34 60 about NIRS. Nørgaard et al²⁰ developed synergy interval PLS (SiPLS) to select several intervals
35
36 61 spectra data which could split the whole wavelength range into a number of intervals and
37
38 62 calculate all possible PLS model combination of 2, 3, or 4 subintervals for optimum prediction.
39
40 63 Furthermoe, the analysis of total polyphenol content is a complex and complicated process. Total
41
42 64 polyphenol contents in cocoa bean is made up of mainly catechin (37%), procyanidins (58%),
43
44 65 and anthocyanins (4%)⁶. These chemical compounds affect both external attributes and internal
45
46 66 chemical properties of polyphenols. For instance, polyphenol in cocoa beans gives some uique
47
48 67 taste and astrigent characteristics known as polyphenol bitterness and astringency²¹ and higher
49
50 68 polyphenol concentration leads to an increase in astrigent-tasting chocolate²² and cocoa liquor
51
52
53
54
55
56
57
58
59
60

1
2
3 69 ²³. Bonvehi and Ventura ²⁴ also, found a correspondence between sensory data and polyphenolic
4
5
6 70 compounds. Moreso, polyphenol imparts a red to purple to brown colour through oxidation of
7
8 71 anthocyanins to quinonic compounds ^{24,25}. For instance, anthocyanins are the most important
9
10 72 group of plant pigment that are responsible for colour ⁶. A single prediction technique can
11
12 73 at most describe one aspect and multiply sensor fusion could prove very useful. Therefore, data
13
14 74 fusion of NIRS and ET is most likely to increase the quantitative prediction performance of total
15
16 75 polyphenols content in cocoa bean.

17
18
19
20 76 Data fusion of sensor is an effective way for the optimum utilization of two or more
21
22 77 sensors, which seeks to combine information from multiple sensors to achieve inferences that are
23
24 78 more feasible than a single sensor ²⁶. Literature information on data fusion is very few. Huang et
25
26 79 al ²⁷ predicted total volatile basic nitrogen in port by data fusion of three sensors techniques,
27
28 80 Winquist et al ²⁸ combined ET and electronic nose for solving classification problem and Ulla
29
30 81 and coworkers ²⁹ also, determined the botanical origin of honey by sensor fusion of ET and
31
32 82 optical spectroscopy. The objectives of this studies were (1) to analyse the total polyphenols
33
34 83 contents in cocoa beans by NIRS spectroscopy and ET, (2) to extract the optimum individual
35
36 84 characteristic variables from each sensor data, and (3) data fusion of NIRS and ET for accurate
37
38 85 and reliable prediction of total polyphenols contents in cocoa beans.

39 86 **2. MATERIALS AND METHODS**

40 87 **2.1. Sample preparation**

41
42
43
44
45
46 88 In this experiment, 110 cocoa bean samples were collected from different cocoa growing
47
48 89 regions of Ghana under the supervision of the quality control division of the Ghana cocoa board.
49
50
51 90 The beans samples were accurately labelled and transported to Jiangsu University, School of
52
53 91 Food and Biological Engineering laboratory for further analysis. Considering the heterogeneities
54
55
56
57
58
59
60

1
2
3 92 of the beans each sample was ground separately for 15 seconds by a small multi-purpose grinder
4
5 93 (QE-100, Zhejiang YiLi Tool Co., Ltd. China). The powders of each sample were sieved with a
6
7
8 94 500 μm mesh before further analysis.
9

10 95 **2.2. NIR Spectra collection**

11
12 96 The spectra of each sample were collected in the reflectance mode by Antaris II Near
13
14 97 Infrared Spectrophotometer (Thermo Electron Company, USA) with an integrating sphere and
15
16 98 the reflectance (R) data were stored as absorbance ($A = \text{Log}(1/R)$). 10 g of the sample was
17
18 99 collected into a standard sample cup and the spectra were scanned three times (after rotating the
19
20 100 cup 120°) with a spectral resolution of 8.0 cm^{-1} . The experiment was conducted at a temperature
21
22 101 of 25°C and at humidity of 60%. Each spectrum was an average of 32 scans in the range of
23
24 102 $4000\text{-}10000 \text{ cm}^{-1}$ and the raw data were measured in 3.856 cm^{-1} interval resulting in 1557
25
26 103 variables. The mean of the three spectra collected from the same cocoa bean sample was used for
27
28 104 subsequent analysis.
29
30
31
32
33

34 105 **2.3 Electronic tongue data acquisition**

35
36 106 The electronic tongue device used was α -Astree brand (Alpha MOS Company, Toulouse,
37
38 107 France). The sensor array used comprises seven potentiometric chemical sensors such as ZZ, BB,
39
40 108 CA, GA, HA, and JB and a reference electrode. The sensitivity of the sensors, differs from the
41
42 109 five tastes; sourness, saltiness, sweetness, bitterness and savoury³⁰. The sensors are made with
43
44 110 silicon transistors and organic coated to ensure that they are sensitive and selective to liquid
45
46 111 samples. 1.0 g of each sample was accurately weighed into a beaker and 100 ml boiled distilled
47
48 112 water added (0.01 gm/l). It was allowed to cool and then filtered through a filter paper. 80 ml of
49
50 113 the filtrate was poured into a beaker and sent to the electronic tongue. Five samples were
51
52
53
54
55
56
57
58
59
60

1
2
3 114 detected at once and the intensity values of each sensor values recorded. The data were collected
4
5 115 at room temperature of 25 °C and humidity of 60%.

8 116 **2.4. Determination of total polyphenols content**

10 117 The determination of total polyphenolic content was done by a colorimetric assay using
11
12 118 Folin-Ciocateu phenol reagent³¹ with few modifications according to Romero-Cortes and co-
13
14
15 119 workers²⁵. The values for the total phenolics were expressed in percentage, in terms of gallic
16
17 120 acid equivalents (g GAE /g of dry matter) with a standard curve of Pearson's correlation
18
19 121 coefficient (R^2)=0.9970. Gallic acid was used because it is more stable and pharmacologically
20
21
22 122 active antioxidant, quantitatively equivalent to most phenolics and gives consistent and
23
24 123 reproducible results³²⁻³⁴. The difference between two parallel measurements was less than 0.10%.

27 124 **2.5 Software**

28
29 125 All calculations and algorithms were carried out in Matlab Version 7.14 (Mathworks Inc.,
30
31
32 126 USA) with Windows 7 ultimate for data processing. Antaris II System (Thermo Electron
33
34 127 Company, USA) was used for spectra acquisition.

36 128 **2.5 Initial data processing**

37
38
39 129 Standard normal variate (SNV)³⁵ was applied on the NIR spectra to remove slope
40
41 130 variation and correct scatter effects due to particle size, so that the performance of PCA and the
42
43 131 model will be based mainly on chemical spectral information³⁶.

44
45
46 132 Si-PLS proposed by Norgaard and co-workers²⁰ was used to select the optimum NIR
47
48 133 spectra wave band range (several subintervals) with the highest predictive performance and the
49
50 134 lowest prediction errors for the analyses of total polyphenols content in cocoa beans. Si-PLS
51
52
53 135 works by splitting the data set into a number of intervals and then calculates accurately all

1
2
3
4 136 possible PLS regression models for all possible combinations of 2, 3, or 4 intervals and the
5
6 137 combination of intervals with the lowest RMSECV for optimum performance are obtained ³⁷.
7
8 138 Furthermore, for the E.tongue data, the last 10 s of the entire 120 s were selected after several
9
10 139 attempt and this time was found to be effective, because they were more stable and this was
11
12 140 similar to other researchers ^{15,30}.

141 **2.7. Calibration and Prediction set**

142 The data set used in this experiment was made up of 110 samples. These were divided
143 into two subsets called: calibration set (80 samples) and prediction set (30 samples). The
144 calibration set was used to develop the model, while the prediction set was used for evaluating
145 the actual predictive ability of the developed models. The individual sample in each set was
146 selected randomly in order to come to approximately 3/1 division of calibration set/prediction
147 set. To avoid bias in subset division, the subset was done as follows: for every 4 samples, about 3
148 were randomly selected as the calibration set while the remaining was used as the prediction set.

149 **2.8. Theory of data fusion techniques**

150 Data fusion techniques are normally classified according to abstraction levels at which
151 data from different instruments are merged ³⁸ and these include: high level abstraction (HLA),
152 mid-level abstraction (MLA) and low-level abstraction (LLA). HLA consists of merging
153 information at a higher level of abstraction that is; combining the results from multiple
154 algorithms to yield a final fused decision (decision making fusion) ²⁶. HLA assumes that data
155 from each sensor system are analyzed as a stand-alone set and afterwards the important features
156 are extracted from each data set before merging them. Thus, the most prominent feature is
157 selected before data integration and this leads to huge data processing with tremendous
158 information losses ²⁷. This approach is biologically inspired, because in the human multisensory

1
2
3 159 systems it is possible to retain the perception of each single sense and, at the same time merge
4
5 160 them together to form a complex judgment³⁹. MLA is also known as feature level fusion, it
6
7
8 161 involves the integration of feature variables of two or more sensor signals. MLA is strong in
9
10 162 keeping enough of the original variables. This approach was previously used to study the
11
12 163 correlation between different instrumental techniques applied to the same samples⁴⁰ and has
13
14 164 recently been used by Huang and co-workers²⁷. LLA refers to original data fusion, it requires
15
16 165 that, all the data from different sensors are simply concatenated before constructing the model⁴¹.
17
18 166 Thus; after data fusion, the data matrix has the number of rows equal to the number of samples
19
20 167 and the number of columns equal to the total number of information from all sources³⁹.
21
22 168 According to Haddi and co-workers⁴¹, the merging of measurements from two sources in LLA
23
24 169 could potentially provide more redundant information and this can grievously affect the results.
25
26 170 To overcome this bottle-neck it is more suitable to couple low-level abstraction to a feature
27
28 171 selection technique⁴² and principal component analysis. Thus, in this study, LLA together with
29
30 172 feature selection technique was employed and PCA was used as sensor fusion technique after
31
32 173 normalization. Among the three data fusion techniques, LLA is mostly used and generally gives
33
34 174 a good results⁴³. Fig.1 shows the process of optimum selection of sensors characteristic variables
35
36 175 and fusion.

176 **Theory of SVMR model**

177 Support vector machine is a strong non-linear multivariate algorithm originally invented
178 by Vapnik in 1995 and the current standard incarnated by Vapnik and Cortes⁴⁴. SVM has
179 recently found its application in food analysis for solving classification and regression problems.
180 SVM algorithm constructs a hyperplane or set of hyperplanes in a high dimensional space for
181 classification, and this principle is also applied to regression tasks⁴⁵. Generally, the higher

1
2
3 182 dimensional space is implemented by a kernel function⁴⁵. There are three classical kernel
4
5 183 functions namely: polynomial kernel function, radial basis function and sigmoid kernel function
6
7
8 184 and the type of kernel function used influences the performance of SVM model. Among these
9
10 185 three kernel functions, radial basis function is mostly selected, because it can handle the linear
11
12 186 and non-linear relationships between the class labels and the spectra data, also it is capable of
13
14 187 reducing the computational complexity of the training set thereby providing a good performance
15
16 188 under general smoothness assumptions⁴⁶⁻⁴⁸. Therefore, in this study, radial basis function was
17
18 189 computed by using equation 1.

21
22
23 190
$$K(x_i, x_j) = \exp\left(\frac{-\|x_i - x_j\|^2}{\gamma^2}\right) \quad (1)$$

24
25

26 191 Where the parameter γ is the bandwidth parameter of the radial basis function

27
28 192 To generate a good performance for SVMR model, penalty parameter C and kernel parameter γ
29
30 193 were optimised in this work. Penalty parameter C determines the trade-off between minimizing
31
32 194 the training error and minimizing model complexity, while kernel parameter γ implicitly defines
33
34 195 the bandwidth of the radial kernel function⁴⁹. The appropriate selection of parameter c and γ
35
36 196 guarantees a satisfactory SVMR results. In this work, the pairs of (C and γ) were tried and the
37
38 197 model with the best performance was chosen.

39 198 **2.9. Development of total polyphenols content prediction model**

40
41
42 199 The total polyphenols content in cocoa beans is very complex and complicated, hence the
43
44 200 relationship between the characteristic variable from a single sensor tends to show low
45
46 201 correlation and appears to be non-linear. In this study, Synergy interval partial least squares (Si-
47
48 202 PLS) was used to select the optimum variables from the SNV pre-treated NIR spectra. Si-PLS is
49
50 203 a very powerful multivariate technique that involves the selection of variables, where the data set
51
52 204 is split into a number of intervals (variable wise) and calculates accurately all possible PLS
53
54
55
56
57
58
59
60

1
2
3 205 model combinations of 2, 3, or 4 intervals. In this study, the full spectral range of 4000-10000
4
5 206 cm^{-1} of the samples were divided into 8, 9, 11, ..., 16 intervals combined with 2, 3, or 4
6
7
8 207 subintervals were used. The optimal combination of intervals and the number of PLS factors
9
10 208 were optimized by cross-validation. The best combinations of intervals (optimum spectra
11
12 209 selection) were chosen according: the lowest root mean square error of cross-validation
13
14
15 210 (RMSECV), root mean square error of prediction (RMSEP) and correlation coefficient (R) by
16
17 211 the equations used by Chen and co-workers³⁷ respectively. Si-PLS model has been used in recent
18
19 212 times in food analysis, and found to be superior to others for selecting optimum spectra interval
20
21
22 213 for accurate prediction^{37, 50}.

23
24 214 After the optimum selection of NIR spectra variables, the last 10 seconds of the E.tongue
25
26 215 sensor data were extracted. Principal component analysis (PCA) was implemented on the
27
28 216 selected variables: NIRS, ET and data fusion, because the characteristic variables of each sensor
29
30 217 contain useful correlation and some redundant information. PCA is a popular dimensionality
31
32 218 reduction technique that is used to eliminate redundant variables and decreases the computational
33
34 219 burden¹⁷. PCA is also among the most popular and effective fusion algorithm²⁶. The top
35
36 220 principal components (PCs) were also extracted from each as the input data for Support vector
37
38 221 machine regression (SVMR) in developing the TPC prediction model respectively. SVMR is a
39
40 222 very powerful non-linear regression based on the classical support vector machine. It has been
41
42 223 widely used and shown its superiority over others; because it has a good generalization property,
43
44 224 self-learning and self-adjustment characteristics and embodies structural minimization principle
45
46 225⁵¹. The number of PCs and some parameters were optimized by cross-validation in calibrating
47
48 226 the model in the calibration set. In this study, the leave one out cross-validation (LOO-CV) was
49
50
51 227 performed⁵² as done by other researchers for RMSECV^{17, 37}. LOO-CV was done as follows:
52
53
54
55
56
57
58
59
60

228 firstly one sample in the calibration set is removed, and the predictive model is built with the
229 remaining samples in the calibration set. The sample removed is then predicted with the model,
230 and the procedure is repeated with each sample left out in the calibration set. LOO-CV is the
231 simplest, and the most common used procedure⁵³. The model's performance was evaluated by
232 these parameters: RMSECV, RMSEP, R and bias as done by other authors^{37,54}.

233 3. RESULTS AND DISCUSSION

234 3.1. Reference measurement of TPC

235 The 110 samples of cocoa bean used in this study showed a wide range of total
236 polyphenols contents as seen from Table 1. These total phenolics were found to be between
237 23.02-33.67% (g GAE/g) and were consistent with other researchers^{55,56}. Furthermore, the range
238 in calibration set cover the range in the prediction set and also the standard deviations in the
239 calibration set and prediction set are not significantly different, therefore the distribution of the
240 samples are appropriate in the two sets³⁷. This means that, bias in the distribution of samples in
241 the two sets were negligible and the distribution of the reference data in the calibration and
242 prediction sets are almost equal.

243 3.2. Selection of optimum NIRS data (Spectral variables)

244 In this study, after SNV pre-processing of NIR spectra, Si-PLS algorithm was used to
245 select optimum spectral variable. The spectrum of 4000-10000 cm^{-1} was divided into 6, 7, ... and
246 20 intervals and the number of intervals were optimized by cross-validation. The lowest
247 RMSECV and the best R were achieved when the full NIR spectrum (4000-10000 cm^{-1}) was
248 split into 11 intervals and the optimum combinations of intervals were [2, 4, 6, and 9]. These
249 intervals corresponds to the spectra range of 4547-5091 cm^{-1} , 5643-6187 cm^{-1} , 6738-7282 cm^{-1}

1
2
3 250 and 8373-8913 cm^{-1} totalling to 83 variables, as shown in Fig.1. The total efficient variables (83)
4
5
6 251 were then analyzed by PCA.

8 252 **3.3. Extraction of optimum Electronic tongue (ET) data**

9
10 253 The taste sensor array measured the dissolved chemical compounds in the solution and
11
12 254 gives the voltage difference between the sensors and the reference electrode (called Ag/AgCl,
13
14
15 255 which as a fixed voltage) i.e. the voltage difference obtained refers to the voltage of the sensor
16
17 256 (V_s) minus the voltage of the reference electrode (V_e), because the dissolved compounds in the
18
19
20 257 solution and the sensor affects the voltage of the given by sensor. After the measurement, each
21
22 258 individual sensor gave a different intensity value based on their selectivity and sensitivity
23
24 259 characteristics to the chemical properties in the cocoa bean samples. However, the response
25
26
27 260 values at the last 10 (110-120) seconds was selected as the optimal range, because it was found
28
29 261 to be more stable and this was similar to other researches^{15,30}. Thus, 7 characteristic variables
30
31
32 262 were obtained as the best selection and were analyzed by PCA.

34 263 **3.4 Data fusion**

35
36 264 After the selection of efficient variables from the two sensors (ET had 7 variables and
37
38
39 265 NIR spectra had 83 variables), each sensor data was scaled by normalization⁵⁷ before PCA. The
40
41 266 data were then merged into one, totalling 90 variables. PCA is a unique technique that is
42
43 267 popularly used for dimensionality reduction with the aim of eliminating redundant variables and
44
45
46 268 diminishing the computational burden⁴⁹. The total variables from the fused data were extracted
47
48 269 as an input data for SVMR modelling. The computed models were compared.

51 270 **3.5. SVMR models of TPC in cocoa beans**

52
53 271 The total polyphenols content in cocoa beans is very complicated; made up of several
54
55 272 phenolic compounds such as theobromine, xanthine, catechin, caffeine, epicatechin, quinones
56
57
58
59
60

1
2
3 273 and anthocyanidins etc. Some of these chemicals influence taste, aroma and colour. For instance,
4
5 274 high polyphenols content is related to bitter-astringency properties of the cocoa beans. Therefore,
6
7
8 275 cocoa beans are normally fermented, because fermentation lessens the bitter-astringent properties
9
10 276 of the beans, an effect that is attributed to loss of polyphenols (flavan-3-ols) during
11
12 277 fermentation^{58,59}. Support vector machine regression (SVMR) as a powerful non-linear
13
14 278 multivariate algorithm was attempted to develop the TPC prediction model in this study, because
15
16 279 it has been found to be superior than other in cocoa beans study^{36,60}. From Table 2 and Fig. 2, it
17
18 280 could be seen that, the best TPC model by SVMR for ET and NIRS were achieved at PCs=5 and
19
20 281 9 respectively. The correlation coefficient (R_{cal}) for ET and NIRS were 0.813 and 0.920 in the
21
22 282 calibration set respectively. From this table it is observed that, when the model was tested in the
23
24 283 prediction set, there was a reduction for both techniques especially for ET techniques. The
25
26 284 performance for ET in the prediction set was $R_{pre}=0.70$, $RMSEP=1.796$ and $bias=0.564$, while
27
28 285 NIRS was $R_{pre}=0.91$, $RMSEP=1.674$ and $bias=0.276$. However, the single sensor in this
29
30 286 experiment could not give the optimum predictive performance therefore, data fusion was
31
32 287 attempted. In fact, the data fusion of different sensor could prove useful. It can acquire more
33
34 288 information than a single sensor and could be used to predict the TPC in cocoa bean samples.
35
36 289 Hence, the model based on data fusion was performed and compared with the single sensors. It
37
38 290 revealed that, the model based on data fusion was found to be superior to the others as seen in
39
40 291 Table 2 and Fig. 3. From Fig. 3 it could be seen that data fusion model was significantly stable in
41
42 292 the prediction set when the mode was tested as compared to the other single techniques. i.e the
43
44 293 differences between $RMSECV$ and $RMSEP$ was not significant. The data fusion results showed
45
46 294 that R_{cal} , $RMSECV$ and $bias$ were 0.987, 0.890 and 0.006 in the calibration set.
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 295 These results could further be explained that, NIRS wavelength range selected by SiPLS
4
5
6 296 had optimum combinations of five intervals [2, 4, 6, and 9] which correspond to 4547-5091 cm^{-1} ,
7
8 297 5643-6187 cm^{-1} , 6738-7282 cm^{-1} and 8373-8913 cm^{-1} that are related to external and some
9
10 298 internal attributes of TPC in cocoa beans. These selected spectra are related to: (4547-5091 cm^{-1})
11
12 299 = CON-H amide combination bands, CH_3 +Alcoholic O-H, (5643-6187 cm^{-1}) = CH_3 , CON-H
13
14 300 amide H-bond first overtone and alcoholic O-H first overtone, (6738-7282 cm^{-1}) = CON-H
15
16 301 amide free first overtone and (8373-8913 cm^{-1}) = CH aromatic + CH_3 second overtone. All these
17
18 302 functional groups are associated with in catechin and theobromine ⁶¹ which are major
19
20 303 components in cocoa bean polyphenols. Also, the first overtone of O-H and -CH stretching
21
22 304 vibration of methyl, methylene, and ethylene are characteristics of functional groups in catechins
23
24 305 and epicatechins ^{8, 62}. In addition, polyphenols correlates with fermented cocoa bean colour ⁶, i.e.
25
26 306 during fermentation polyphenol oxidases converts polyphenols into quinones and these
27
28 307 complexes with other polyphenols to give rise to brown colouration ^{22, 63}. Also, anthocyanins are
29
30 308 known to be plant pigments that are responsible for colour ⁶.

31
32 309 On the other hand, the ET data provided information on the bitter astringent property of
33
34 310 the cocoa beans that could be related to some part of the phenolic compounds especially, flavan-
35
36 311 3-ols as it is related to the bitter-astringent properties of cocoa beans ²¹. Furthermore, higher
37
38 312 concentration of polyphenols was found to contribute to very astringent-tasting chocolate ²². Also,
39
40 313 Bonvehi and Ventura ²⁴ found a correspondence between sensory data and polyphenolic
41
42 314 compounds. Therefore, the model based data fusion provided both internal and external attributes
43
44 315 that are directly related to total polyphenols contents in cocoa beans.

318 4. CONCLUSIONS

319 This work has demonstrated the feasibility of integrating NIR spectroscopy and
320 Electronic tongue technique for an improved prediction of total polyphenols content in cocoa
321 beans. Data fusion of NIRS and ET together with SVMR algorithm could be attempted for other
322 related quality parameters. The overall results have proved that, data fusion (NIRS and ET)
323 technique could improve the efficiency of measuring total polyphenols content in cocoa beans.
