

Analytical Methods

Accepted Manuscript

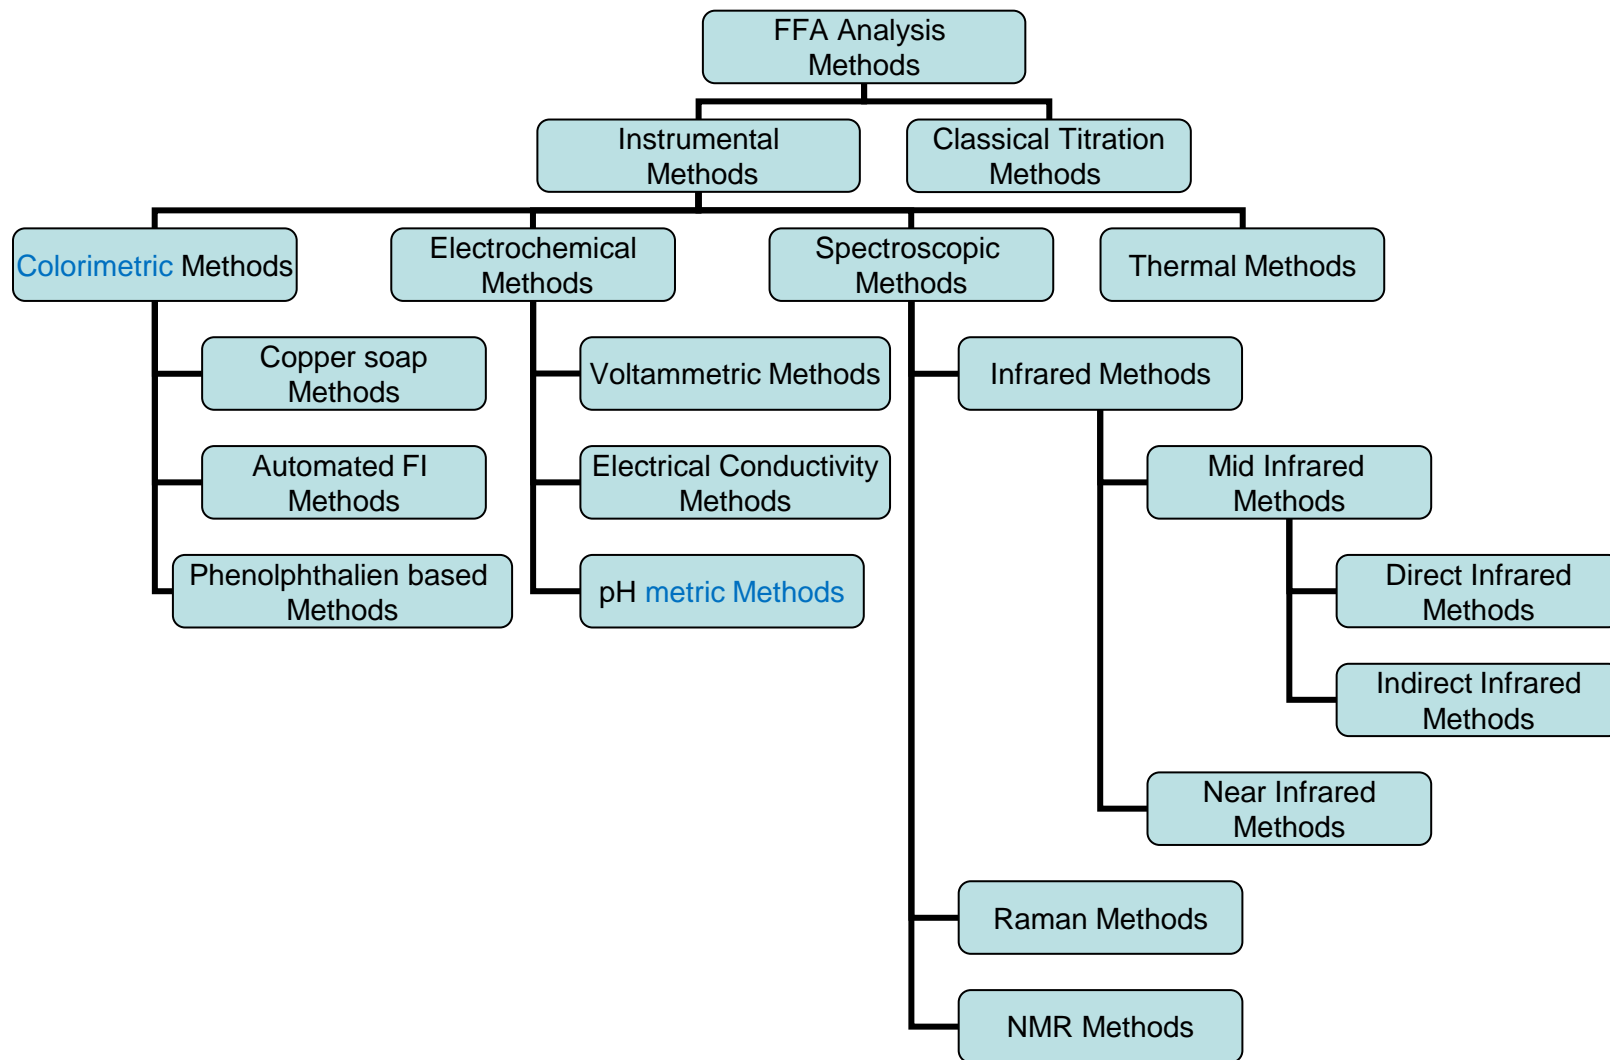

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

9 **Abstract**

10 Basically, free fatty acids (FFAs) are produced by hydrolysis of oils and fats. Level of
11 FFA depends on time, temperature and moisture content because the oils and fats are
12 exposed to various environments such as storage, processing, heating or frying. As FFAs
13 are less stable as compared to neutral oil therefore they are more prone to oxidation and
14 produce rancidity. Thus, FFA is a key feature linked with the quality and commercial
15 value of oils and fats. American Oil Chemists' Society (AOCS), Association of Official
16 Analytical Chemists (AOAC) and European Commission Regulation (EEC) have
17 established almost identical standard methods for the assessment of FFA. These methods
18 are based on the titration where oils or fats are needed to be dissolved in hot neutralized
19 ethanol or ethanol/diethyl ether using phenolphthalein as an end point indicator.
20 Titrimetric procedures are however laborious and need large amount of chemicals and
21 solvents. Besides cost of chemicals, environmental issues further limit these procedures.
22 In addition, accurate detection of end point especially for highly colored crude oil by
23 colorimetric indicator is a difficult task. Despite all mentioned demerits, unfortunately

1
2
3
4 24 titration method is still being used in most of the edible oil industries for the
5
6 25 determination of FFA. Due to lack of any comprehensive review on this very important
7
8 26 topic, we have made an attempt to present a review in order to discuss various available
9
10 27 methods with special emphasis on the instrumental methods due to their high sensitivity,
11
12
13 28 accuracy and rapidity.

1. Introduction

Vegetable oils or fats are extracted from the oilseeds in the crude form. Various refining stages such as degumming, neutralization, dewaxing, bleaching and deodorization are followed to convert extracted crude oils to edible oils. During processing, a number of parameters such as moisture, peroxide value, free fatty acids (FFAs), saponification value (SV) and iodine value (IV) are monitored. Among these parameters FFA content is considered as a very crucial factor and linked with the quality as well as economic value of edible oils.¹ Generally FFAs are the hydrolysis product generating as a result of the oil and fat oxidation during long time storage or processing at elevated temperature and heating or frying. Initially, AOCS², AOAC³ and European Commission Regulation (EEC)⁴ have recommended standard methods for the determination of FFA. These methods are almost similar and based on the titration of oil (3.5-56.4 g). Oils or fats are dissolved in hot neutralized 95% ethanol (50-100 ml) or ethanol/diethyl ether (50-150 ml), against a strong base using phenolphthalein as an indicator. Although, these titrimetric methods are very simple but extremely laborious and need large amount of expensive chemicals associated with environmental issues. Furthermore, the analysis of dark crude oils in the presence of colorimetric indicator is very problematic to find out the accurate end point during titration.

To overcome such issues, a number of instrumental methods have been developed as potential alternative to classical methods for more accurate and sensitive measurement of FFA contents in the edible oils and fats. In general these methods can be categorized into three major groups:

(a) Colorimetric methods

1
2
3 65 (b) Spectroscopic methods
4

5 66 (c) Electrochemical methods
6
7

8 67 Generally, second and third group involves variety of sophisticated instruments with
9
10 68 diverse approach that compete with each other in terms of speed of analysis, amenability
11
12 69 to automation and reduction of harmful solvents. Some instrumental methods provide a
13
14 70 significant gain in accuracy and sensitivity than classical titrimetric methods.
15
16

17 71 Several methods have been reported during the last sixty year. In 1950s,
18
19 72 spectrophotometric technique was well addressed and several workers published plenty
20
21 73 of articles on FFA using colorimetric methods. After that, the trend changed towards the
22
23 74 electrochemical techniques. In last two decades, attention was however focused on use of
24
25 75 infrared spectroscopic methods for the direct or indirect determination of FFA. These
26
27 76 methods were claimed to be environmental friendly as either chemicals are totally
28
29 77 avoided or require negligible amount of chemicals as well as samples. Fig. 1 shows the
30
31 78 block diagram of the methods developed for the determination of FFA during last few
32
33 79 decades. To the best of our knowledge there is no any comprehensive review available on
34
35 80 FFA analysis. Therefore, present review will explore many methods which were
36
37 81 developed in last few decades.

88 2. Discussion

89 2.1. Colorimetric methods

90 Various colorimetric methods have been reported by several researchers.

91 2.1.1. Copper soap method

92 In 1956, Ayers⁵ made his first effort to determine the FFA by calorimetric method.
93 According to his procedure, aqueous solution of copper or cobalt nitrate was used to
94 convert FFA into water-insoluble soaps. Colored soap precipitate was extracted with
95 chloroform and quantification was carried out by measuring absorbance at 675 and 527
96 nm for copper and cobalt, respectively. Although method was not proposed for FFA
97 analysis but it provided a base to develop colorimetric methods for FFA analysis in edible
98 oils. Later on Baker⁶ proposed an improved copper salt based method which was
99 designed particularly for FFA analysis in edible oils. The method involves the dissolution
100 of oil in benzene followed by mixing with aqueous cupric acetate solution. The mixture
101 was centrifuged and quantification of FFA was determined by measuring the absorption
102 of benzene layer at 640 nm. This method showed good correlation with titrimetric
103 method. The only limitation of this method was the dissolution of some copper salts of
104 saturated fatty acids in benzene. In view of the inconsistencies in working wavelength of
105 640 vs 675 nm^{5,6}, Bains *et al.*,⁷ examined the spectra and the effect on color of oil during
106 the measurement. He concluded that 670 nm was the optimum wavelength for copper
107 soaps in non-colored or colored oils. Twelve years later, Lowry and Tinsley⁸ reported a
108 substantial work to optimize the method in terms of sensitivity and reproducibility. The
109 conclusion of his work was the stabilization of the copper soap of saturated fatty acids in
110 benzene and improvement in the sensitivity by controlling the pH using pyridine. Due to

1
2
3 111 the practical and health concerns of benzene, various authors used alternative to benzene
4
5 112 such as toluene ⁹, isooctane ¹⁰ and cyclohexane ¹¹. Gyrik *et al.*, ¹² proposed a new
6
7
8 113 analytical tool for the determination of total FFA content in thermally treated cooking oil.
9
10 114 The method was based on the colorimetric copper soap combined with the concept of
11
12 115 optothermal window (OW) (with 632.8 nm He - Ne laser used as a radiation source). The
13
14
15 116 results obtained by this method were compared to those acquired by conventional
16
17
18 117 spectroscopy; the correlation between the two methods was high for FFA concentrations
19
20 118 exceeding 2 $\mu\text{mol/ml}$.

21
22 119

23 24 25 120 2.1.2. Automated FIA systems

26
27 121 The first automated system for FFA analysis in edible oils using copper soap method was
28
29 122 introduced in 1980's. ⁹ The automation was accomplished using a flow injection analysis
30
31 123 (FIA) system which was able to analyze up to 20 samples/h. In contrast to the previously
32
33 124 published methods, based on organic solvents, the quantification was done in the aqueous
34
35 125 phase. However, the system did not receive much attention, because of the complications
36
37 126 and stability problems. Later on an improved hardware in FIA system using a single-
38
39 127 extraction step was reported. ¹³ This new system offered enhanced stability and much
40
41 128 shorter analysis time (130 samples/h). The only shortcoming of the system was poor
42
43 129 sensitivity. Puchades *et al.*, ¹⁴ improved the sensitivity of FIA systems through optimized
44
45 130 operating conditions, for example pH, flow rate, tubing length/diameter, and oil/solvent
46
47 131 proportion resulted in better analysis speed (75 samples/h) and lower limit of detection
48
49 132 (~0.01% FFA). Despite the mentioned improvements the method did not receive much
50
51
52
53
54
55
56
57
58
59
60

1
2
3 133 attention due to the complications in the analysis and incompatible values as compared to
4
5 134 the official method.
6
7

8 135 A continuous liquid-liquid extraction system using a single-channel flow-reversal
9
10 136 injection mode was also proposed for the direct determination.¹⁵ The results provided by
11
12 137 the proposed method were in accordance with those obtained by a manual procedure and
13
14 138 comparable to the standard acid-base titration method, but the sampling frequency was
15
16 139 lower (12 samples/h).
17
18

19 140 2.1.3. Phenolphthalein based method

20
21
22 141 Due to the shortcomings of the official method, Linares *et al.*,¹⁶ made an attempt to
23
24 142 automate the official method. He used the same reagents as the IUPAC official method,
25
26 143 whilst quantification was based on monitoring the decrease in the phenolphthalein (PHP)
27
28 144 intensity at 562 nm as a result of the reaction between KOH and FFA in the oil sample.
29
30 145 The analytical range of method was 0.15-0.81% FFA and sample throughput up to ~ 60
31
32 146 samples/h. Later on a modified method with similar analytical range was reported¹⁷ using
33
34 147 3-7 ml of inexpensive 1-propanol as a diluent and carrier in comparison to the huge
35
36 148 amount of solvents in official method. The sample throughput was 30-100 samples/h.
37
38

39
40
41 149 A direct measurement of FFA in virgin olive oil without dilution was reported using
42
43 150 similar system.¹⁸ The system was equipped with an optical fiber beam connected to the
44
45 151 spectrophotometer set at 562 nm. The system had the same sensitivity as the previous
46
47 152 methods with a sample throughput of 12-60 samples/h. Afterward an indirect titrimetric
48
49 153 method was developed based on the complete extraction of acids from oil into reagent
50
51 154 (0.05 mol dm⁻³ triethanolamine in the mixture of 50 % H₂O + 50 % 2-PrOH) and indirect
52
53 155 titration of acids in BH⁺ form against aqueous alkali in the presence of a PHP indicator.¹⁹
54
55
56
57
58
59
60

1
2
3 156 The benefits of proposed method included the lack of toxic solvents, analysis at room
4
5 157 temperature and no need for preliminary neutralization of acid admixtures.
6
7

8 158
9
10 159 Saad *et al.*,²⁰ reported a single and two-line manifold FI methods using PHP and
11
12 160 bromothymol blue (BTB) as indicators. The method was based on the monitoring of the
13
14 161 changes of absorbance of the indicators at 562 nm for PHP and 627 for BTB. Various FI
15
16 162 parameters were optimized such as carrier and reagent concentration, length of reaction
17
18 163 coil, flow-rate, injected volume and size of mixing chamber. The single-line manifold
19
20 164 with PHP as indicator was recommended for the determination of samples with acidity
21
22 165 higher than 0.4, while for lower acidities (< 0.4) a two-line manifold with BTB was
23
24 166 recommended. The method was linear over the range 0.4-10.0 FFA for single-line
25
26 167 manifold and 0.11-0.50 FFA for the two-line manifold. Sample throughputs were 35-74
27
28 168 and 21-46 samples/h for single-line and two-line manifolds, respectively.
29
30
31
32

33 169
34
35 170 A non-aqueous single-line manifold system was built by modification of an HPLC for
36
37 171 FIA.²¹ Oil samples were injected without pre-treatment into a *n*-propanol solution
38
39 172 containing KOH and PHP. The linear concentration range was calculated as 0.09–1.50
40
41 173 and 0.07–1.40 FFA% for corn and sunflower oils, respectively. The results were
42
43 174 comparable with those obtained by the AOCS method. The benefits of proposed method
44
45 175 were its simplicity and high sample throughput.
46
47
48

49 176
50
51 177 Makahleh and Saad²² reported a single line FIA method attached with capacitively
52
53 178 coupled contactless conductivity detector (C⁴D). Methanol mixed with 1.5 mM sodium
54
55 179 acetate (pH 8) 80:20 (v/v) was used as a carrier stream at a flow rate of 1.0 mL min⁻¹.
56
57
58
59
60

1
2
3
4 180 Good agreement was found between the standard non-aqueous titrimetry method and the
5
6 181 proposed method. The proposed method offers high sampling rate of 40–60 sample/h
7
8 182 and considerably low cost automated system that needs minimum human intervention
9
10 183 over long periods of time. Recently a visual and green titrimetric method was proposed
11
12 184 using PHP as an indicator.²³ The sample was dissolved in a water–ethanol mixture (1:1
13
14
15 185 v/v) and titrated with a 0.02 mol L⁻¹ aqueous NaOH solution. The results obtained by
16
17 186 proposed approach were comparable with AOCS titration method.
18
19

20 187

21 188 2.1.4. Miscellaneous spectrophotometric methods

22
23
24 189 A new approach for the FFA determination in non aqueous medium without titration was
25
26 190 reported in the literature.^{24,25} The method utilized phenol red as fatty acid indicator,
27
28 191 which was solubilized in reverse micelles formed by AOT [sodiumbis(2-ethylhexyl)
29
30 192 sulfosuccinate] in isooctane. Quantification was achieved by monitoring the changes in
31
32 193 absorbance at 560 nm (disappearance of the red color). Although the method was
33
34 194 economical (small amounts of samples and solvents) but found to be lacking in accuracy.
35
36 195 Therefore, no any additional efforts were made for its improvement. Rejeb and Gargouri
37
38 196 ²⁶ reported a new method for the determination of olive oil acidity. The method was
39
40 197 based on the measurement of polyunsaturated free fatty acids reacting with lipoxygenase.
41
42 198 Hydroperoxy-fatty acids enzymatically formed were easily determined by UV
43
44 199 spectrophotometry at 234nm. The proposed method was successfully applied for the
45
46 200 determination of acidity in olive oil samples and good agreement was obtained between
47
48 201 the proposed enzymatic method and classical titration method. This method was accurate,
49
50 202 simple, sensitive, inexpensive, and reliable for acidity determination of olive oil with a
51
52
53
54
55
56
57
58
59
60

1
2
3 203 high sample throughput. Recently, Fedosov *et al.*,²⁷ developed a novel microtitration
4
5 204 method for determining the FFA in small samples of oil (5–150 mg). The method was
6
7
8 205 based on the optical signal of pyranine (aqueous pK 7.3), which changed its absorbance
9
10 206 and fluorescence. All reactants were dissolved in a medium with universal solubility,
11
12 207 which allowed accurate optical measurements on conventional equipment. Titration
13
14 208 curves for FFA standards stipulated the selection of the neutralization point. Comparison
15
16 209 of fluorescence and absorbance of pyranine pointed to somewhat better “signal to noise”
17
18 210 properties of the fluorescent signal when working with heavily pigmented oil samples.
19
20 211 Blind examination of different experimental mixtures (FFA = 0.15–40 %) revealed a
21
22 212 good correspondence between the pyranine method and official method. Furthermore, it
23
24 213 was reported that the small size of optical cells could allow further minimization of the
25
26 214 pyranine assay if adapting it to an automated procedure.
27
28
29
30
31
32

33 216 **2.2. Electrochemical methods**

34 217 2.2.1. Voltammetric technique

35
36 218 Voltammetry is an important class of electrochemical methods widely used in analytical
37
38 219 chemistry and various industrial processes. In voltammetry, information about an analyte
39
40 220 is obtained by measuring the current as the potential is varied.²⁸ It is commonly used for
41
42 221 compounds that are readily oxidized/reduced to provide highly selective and sensitive
43
44 222 quantitative methods. Electrochemically FFA are weakly active and can be reduced or
45
46 223 oxidized. The voltammetric behavior of quinone in the presence of acids in buffered
47
48 224 protic solvents was first reported by Takamura and Hayakawa.²⁹ It was reported that
49
50 225 reduced form of quinone (dissolved in ethanol) gave a very strong voltammetric signal in
51
52 226 presence of acids. For FFA analysis in edible oils the behavior of quinone has been
53
54
55
56
57
58
59
60

1
2
3 227 utilized by various authors³⁰⁻³⁴ to develop HPLC and FIA methods. The FIA system
4
5 228 coupled with voltammetric detection had high sensitivity, better reproducibility, low
6
7
8 229 solvent consumption and excellent throughput of 60 samples/h. Unfortunately this
9
10 230 technique did not receive much attention. Li *et al.*,³⁵ proposed a new method using
11
12 231 polypyrrole-modified electrode in linear potential sweep voltammetric mode. In this
13
14 232 method, the behavior of naphthoquinone in the presence of FFA was investigated in
15
16 233 ethanol/1,2-dichloroethane (3:1) solution containing 0.1 M LiClO₄. A linear calibration
17
18 234 graph was obtained in the range of 5.0×10^{-6} – 6×10^{-3} M for FFA ($R = 0.993$), with
19
20 235 sensitivity of 2.41×10^{-2} A L/mol and a limit of detection 1.2×10^{-6} M. The method was
21
22 236 accurate, superior in sensitivity and capable to analyze 45 samples/h.
23
24
25
26
27
28

29 238 2.2.2. Electrical Conductivity method

30 239
31
32 240 Recently a new approach for the determination of FFA in edible oils based on the
33
34 241 electrical conductivity (EC) value change of a 0.04 M potassium hydroxide (KOH)
35
36 242 solution during KOH–FFA mixed reaction was reported.³⁶ The EC value changes of the
37
38 243 KOH solution layers were determined, and the FFA was determined from calibration
39
40 244 plot. Various parameters were optimized like the concentration of KOH solution, holding
41
42 245 time, the types of edible oils, setting temperature, and the ratio of oil to KOH solution
43
44 246 (m/v). The method was validated using standard addition and the AOCS method. The
45
46 247 results and analytical performance of the EC procedure was better than that of the AOCS
47
48 248 method.
49
50
51
52
53
54
55
56
57
58
59
60

251 2.2.3. pH-metric methods

252 In general the low polarity and high viscosity of oils have made it impractical to use pH
253 metric methods for the determination of FFA. Lapshina *et al.*,³⁷ carried out pH metric
254 measurements by extracting FFA from oil into a polar solvent. In order to facilitate
255 extraction, the author suggested the use of a weak base triethanolamine (TEA) in an
256 appropriate solvent mixture (diethyl ether 80%, chloroform 19% and water 1%) to
257 convert carboxylic acids into their salts. Although the method was workable but showed
258 poor reproducibility because of instability of the electrode and the basic reagent in the
259 solvent mixture. Later on the method was modified by replacing the triethanolamine with
260 a 1:1 (v:v) mixture of iso-propanol and water containing 0.2 M TEA and 0.02 M
261 KNO_3 .³⁸⁻⁴¹ Rather than extracting FFA, this solvent mixture effectively makes an
262 emulsion in the range of pH measurement. Soon after, Velasco-Arjona and Luque de
263 Castro⁴² proposed a fully automated method using robotic station for the determination
264 of AV in olive oil without titration based on pH measurements of emulsion. The excellent
265 correlation with potentiometric titration demonstrated the convenience of the automated
266 method. This method was able to analyze 15 samples/h. Various publications on this
267 approach were reported for acidity measurements in oilseeds.⁴³⁻⁴⁵ A new concept of flow
268 titration was proposed using sequential injection analysis (SIA) with a diode array
269 spectrophotometric detector linked with a multivariate curve resolution-alternating least
270 squares (MCR-ALS) in the presence of alizarine indicator.⁴⁶ Total waste generated in this
271 method was 3.33 ml (0.41 ml of sample, 0.25 ml of indicator and 3 ml of carrier). The
272 results of the proposed method compared well with tritrimetric method and the frequency
273 of the analysis was 12 samples/h.

1
2
3 274 **2.3. Spectroscopic methods**
4

5 275 2.3.1. Infrared methods
6

7 276 2.3.1.1. Direct Infrared methods
8

9
10 277 The possibility of utilizing FTIR spectroscopy for FFA analysis has been examined by
11
12 278 number of scientists over the last two decades. Lanser *et al.*,⁴⁷ first time reported a semi
13
14 279 quantitative method for the analysis of FFA in soybean oils by computer-assisted FTIR
15
16 280 using deconvolution technique. He collected the spectra of oils using transmission cell,
17
18 281 and observed the spectral changes in the carbonyl region in the range 2000-1600 cm⁻¹, and
19
20 282 correlated to the FFA content obtained by the standard AOCS method. The method was
21
22 283 based on developing a calibration plot using oleic acid as standard into FFA-free soybean
23
24 284 oil. A major restriction to make the method more quantitative was the spectral variation
25
26 285 of ester band among various oils, because the carboxylic acid C=O absorption appears on
27
28 286 the shoulder of triglyceride ester linkage absorption.
29

30
31
32
33
34 287 Later on an accurate method was developed based on the measurement of the carboxylic
35
36 288 acid C=O band at 1711 cm⁻¹ using transmission approach, covering an analytical range of
37
38 289 0.2–8% FFA.⁴⁸ To avoid the matrix effects noted earlier⁴⁷, the ratioed out calibration and
39
40 290 sample spectra against the spectrum of a FFA-free oil of the same type of oil were
41
42 291 analyzed rather than a background spectrum of air. This approach gave results
43
44 292 comparable in precision and accuracy to that of the AOCS reference titration method.
45
46 293 Through macroprogramming the method was completely automated, this approach takes
47
48 294 an analysis time less than 2 min.
49

50
51
52
53 295
54
55
56
57
58
59
60

1
2
3 296 After the above preliminary studies, a new procedure was reported for FFA in olive oil
4
5 297 based on attenuated total reflectance (ATR) FTIR spectroscopic measurements using
6
7
8 298 partial least-squares regression (PLSR).⁴⁹ The developed method was applicable to
9
10 299 samples of different categories of olive oil with analysis time of 5 min/sample. Che Man
11
12 300 *et al.*,⁵⁰⁻⁵¹ described transmission FTIR spectroscopic methods using 200 μm NaCl
13
14 301 windows for low level of FFA contents in palm olein (PO) and 100 μm BaF₂ windows for
15
16 302 higher FFA in crude palm oil (CPO). The PLS calibration models were developed to
17
18 303 correlate FTIR and chemical method. The developed method drastically reduced the
19
20 304 analysis time to less than 2 min/sample. Verleyen *et al.*,⁵² followed up more rigorously
21
22 305 research on the work previously reported⁴⁷ and developed effective calibrations for
23
24 306 different oils (corn, soybean, sunflower, palm, palm kernel, and coconut oils). It was
25
26 307 concluded the calibration models developed for the six oils differed significantly and
27
28 308 indicated the need to develop a calibration for each specific oil or fat.
29
30 309 Inon *et al.*,⁵³ developed the chemometric based method using PLS multivariate calibration
31
32 310 and net analyte signal (NAS) preprocessing for the determination of FFA in commercial
33
34 311 olive oil samples of different types and origins. The limit of detection (LOD), sensitivity
35
36 312 and selectivity of the methodology developed were evaluated in terms of the net analyte
37
38 313 signal and found LOD value of 0.072%, with sensitivity of 0.077 in terms of per unit
39
40 314 concentration.
41
42 315 Due to the practical limitations of transmission spectroscopy for the quantification of
43
44 316 higher FFA, a simple and direct methodology was developed for the determination of
45
46 317 higher FFA contents (>30) by single bounce (SB) ATR FTIR spectroscopy in poultry
47
48 318 feed lipids⁵⁴, deodorizer distillates and crude oils.⁵⁵ The accuracies of the methods were
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 319 checked by comparison to a conventional AOCS titrimetric procedure. Yu *et al.*,⁵⁶⁻⁵⁷
4
5 320 reported a new approach for the automated determination of FFA in edible oils using
6
7 321 spectral reconstitution (SR) technique. The data obtained by this technique was accurate
8
9 322 and reproducible. The developed automated method was capable of analysing ~90
10
11 323 samples/h; a rate appropriate with the throughput required by commercial contract or
12
13 324 high-volume process control laboratories.
14
15
16
17
18
19

20 326 2.3.1.2. Indirect infrared methods

21
22 327 For fats and oils that may have undergone significant thermal stress or extensive
23
24 328 oxidation, an indirect FTIR spectroscopic method was developed for FFA based on ATR
25
26 329 approach in order to remove the matrix effect.⁴⁸ The 1% KOH/methanol was used to
27
28 330 extract the FFA and convert them to their potassium salts. The carboxylate anion absorbs
29
30 331 at 1570 cm^{-1} , well away from interfering absorptions of carbonyl commonly present in
31
32 332 oxidized oils. To overcome the matrix effects the indirect method was more sensitive and
33
34 333 accurate than the direct determination of FFA, although the method complicated the
35
36 334 analysis. An automated flow injection system was developed for the rapid determination
37
38 335 of the FFA content in olive, sunflower, and corn oils.⁵⁸ The method was based on the
39
40 336 indirect approach⁴⁸ to avoid the matrix effects linked with direct measurements of
41
42 337 carboxylic acid band at 1711 cm^{-1} . This automated method was able to analyze ~40
43
44 338 samples/h.
45
46
47

49
50

51 339
52
53 340 A transmission spectroscopic method using potassium phthalimide (K-phthal) as a weak
54
55 341 base to convert the FFA present in oils to their carboxylate salts without causing oil
56
57
58
59
60

1
2
3 342 saponification was reported.⁵⁹ The method was automatable, and capable of analyzing
4
5 343 about 60 samples/h. Later on a sensitive and rapid methodology for the quantification of
6
7 344 a low levels (<0.005%) of FFA in edible oils was described using sodium hydrogen
8
9 345 cyanamide (NaHNCN) to convert FFA to their carboxylate salts.⁶⁰⁻⁶¹ The feasibility of
10
11 346 employing a portable variable filter array (VFA) IR spectrometer equipped with a
12
13 347 transmission flow cell for FFA analysis was reported by Li *et al.*⁶² The indirect approach
14
15 348 was employed to convert the FFA to their salts as described earlier.⁶⁰⁻⁶¹ Based on this
16
17 349 measurement, a VFA-IR spectrometer provided an economical instrumental means for at-
18
19 350 line monitoring of FFA levels in crude and refined edible oils capable of analyzing ~20-
20
21 351 30 samples/h. Aryee *et al.*,⁶³ determined FFA content in fish oils employing same
22
23 352 approach. It was reported that FTIR method is a flexible and viable instrumental
24
25 353 alternative to the standard titrimetric method.
26
27
28
29

31
32
33

34 355 2.3.2. Near infrared methods

35
36 356 The near infrared (NIR) methods for the analysis of FFA in oils and fats were reported
37
38 357 before the mid infrared (MIR) methods. Frankel *et al.*,⁶⁴ used NIR spectroscopy for the
39
40 358 first time to determine the quality of the soybeans and its oil stored at different moisture
41
42 359 levels. He observed that NIR analysis at 2260 nm showed a good correlation coefficient
43
44 360 of 0.864 with titratable FFA. Furthermore, it was reported that NIR analysis is most
45
46 361 suitable and rapid to evaluate hydrolytic deterioration in stored soybeans. This
47
48 362 methodology was used to evaluate the factors affecting the food quality of soybeans for
49
50 363 domestic and foreign markets.
51
52
53
54
55
56
57
58
59
60

1
2
3 365 After the initial work of Frankel *et al.*,⁶⁴ there was no any further work carried out on NIR
4
5 366 for ten years. Majority of the methods were developed on mid IR range. In 1997, a direct
6
7 367 method for the determination of FFA in fish oil was reported.⁶⁵ PLS and multiple linear
8
9 368 regression (MLR) was used for calibration and described that first derivative
10
11 369 mathematical treatment provided better results as compared to the second derivative and
12
13 370 *N*-point smoothing for NIR spectra. The calibration equation for FFA obtained from PLS
14
15 371 was found better as compared to the MLR.
16
17
18
19
20
21
22

23 373 CheMan *et al.*,⁶⁶ developed a calibration for the determination of FFA in crude palm oil
24
25 374 and its fractions based on the NIR reflectance approach. For the preparation of FFA
26
27 375 calibration, oil was hydrolyzed with 0.15% (w/w) lipase in an incubator at 60°C (200
28
29 376 rpm). The optimized calibration models were constructed with MLR analysis based on
30
31 377 C=O overtone regions from 1850–2050 nm. Calibrations were validated with an
32
33 378 independent set of 8–10 samples. The developed method was rapid, and its accuracy was
34
35 379 generally good for raw-material quality control. The method was capable to analyze 12
36
37 380 samples/h. The hydrolytic degradation of lipids in fish oil was monitored in
38
39 381 transmittance mode by an NIR monochromator instrument in the range of 1100–
40
41 382 2500 nm.⁶⁷ For FFA analysis PLS regression calibration model was performed. The
42
43 383 accuracy of the developed model was tested using a validation set. It was reported that
44
45 384 NIR spectroscopy with PLS regression could be successfully used to monitor hydrolytic
46
47 385 degradation of lipids in the fish oil stored under industrial conditions.
48
49
50

52
53
54
55
56
57
58
59
60

386

1
2
3 387 A novel method was developed for the estimation of FFA content directly in high-oleic
4
5 388 sunflower seeds.⁶⁸ For the calibration a sample set of different varieties from the harvest
6
7
8 389 of 2004 and 2005 was used. The developed NIR spectroscopic calibration was calculated
9
10 390 with a modified PLS algorithm, standard normal variate (SNV), detrend scatter correction
11
12 391 and the 2nd derivative of the spectra of ground sunflower seeds. The results obtained by
13
14
15 392 this method demonstrated the efficiency and cost effectiveness of the NIR method for the
16
17
18 393 evaluation of FFA content in sunflower seeds.

394

21 395 Ng *et al.*,⁶⁹ described a transmission based method using PLS and forward stepwise
22
23
24 396 multiple linear regression (FSMLR) techniques for FFA in frying oils. PLS model
25
26 397 provided improved results compared to FSMLR model when derivative as spectral
27
28
29 398 treatment used in the region of 700-1100 nm. The best correlations between the NIR and
30
31 399 wet chemical method for FFA was 0.943. Where as in the longer wavelength region
32
33
34 400 (1100-2500 nm) FSMLR model was better than PLS model. The developed method was
35
36 401 capable to analyze 20 samples/h. Many authors used NIR calibration for FFA
37
38 402 quantification in the oxidation⁷⁰ and interesterification of oil⁷¹ to replace the traditional
39
40
41 403 methods. Furthermore it was reported that NIR spectroscopy might be adapted for real-
42
43 404 time quality control purposes. Recently, Yu *et al.*,⁷² reported an automatic determination
44
45 405 of acid value in edible oils by NIR spectrometer coupled with continuous samples
46
47
48 406 injection cell using edible oils as raw materials. The R² and the RMSEP of the calibration
49
50 407 for acid value were 0.9873 and 0.114 mg/g in the range of 5500-4600 cm⁻¹ with baseline
51
52 408 correction point at 6524 cm⁻¹ and 4823 cm⁻¹ and SNV. By this method analysis rate could
53
54
55 409 be achieved as 90 samples/h.

410

2.3.3. Raman spectrometry

Fourier transform (FT) Raman spectrometry in combination with PLS regression was used for direct reagent-free determination of FFA content in olive oils and olives. Oils were directly investigated in a simple flow cell, while olives were measured in a dedicated sample cup, which was rotated eccentrically to the horizontal laser beam during spectrum acquisition. External and internal (leave-one-out) validation were used to assess the predictive ability of the PLS calibration models for FFA content in oil and olives in the range 0.20–6.14 and 0.15–3.79%, respectively.⁷³ The results obtained by the proposed procedures could be used for screening of good quality olives before processing, as well as, for the on-line control of the production of oil.

El-Abassy⁷⁴ reported a visible Raman spectroscopic method for determining the FFA in extra virgin olive oil using PLS. For the calibration, oleic acid was used to increase the FFA content in extra virgin olive oil up to 0.80%. The calibration curve of actual FFA% obtained by titration versus predicted values based on the Raman spectral regions 1600-945 cm^{-1} provided a robust and precise model with high accuracy for the prediction of the FFA%. Although the methods were simple and accurate, but high cost of the instrument restricted the use of this technique in the routine analysis.

2.3.4. Nuclear magnetic resonance spectroscopy

Nuclear magnetic resonance (NMR) spectroscopy is increasingly applied to the analysis of food and food components. In the field of edible oils and fats, NMR provides useful information on the lipid class composition (the relative amount of triacylglycerols, diacylglycerols, FFA, sterols, phospholipids, and other minor components). The determination of FFA by NMR was first studied on the lipids extracted from albacore

1
2
3 435 tuna (*Thunnus alalunga*) using high-resolution ^{13}C NMR spectroscopy.⁷⁵ FFA carbonyl
4
5 436 resonances were detected at the lower field of the ^{13}C NMR carbonyl region and used for
6
7
8 437 its quantitative determination. NMR data agreed with those obtained using UV
9
10 438 spectrophotometry, showed that NMR is a suitable method to follow lipolytic alterations.
11
12 439 It was mentioned the method could be used to monitor the changes in fish lipids and oils
13
14 440 during processing or storage. Sun and Moreira⁷⁶ studied the correlation between NMR
15
16 441 proton relaxation times and the increase in FFA in soybean oil degradation. Soybean oil
17
18 442 was degraded by heating only and by frying corn tortilla dough for 10 min/h up to 50 h.
19
20 443 Both AOCS and NMR methods were used to determine the extent of oil degradation.
21
22 444 Results showed that FFA increased as heating time increased. The longitudinal relaxation
23
24 445 time (T_1) and the transverse relaxation time (T_2) decreased as oil degradation increased.
25
26 446 There was a linear relationship between NMR and AOCS measurements. The number of
27
28 447 methods reported on ^{13}C NMR^{77,78}, ^{31}P NMR⁷⁹, and ^1H NMR for FFA in vegetable oils.⁷⁸
29
30 448 ⁸⁰ Although the developed methods were easy, rapid and simple and could be used as a
31
32 449 promising tool for online quality control, but did not received much attention from the
33
34 450 industry due to the high price of the NMR equipment and technical skills.
35
36
37
38
39
40
41
42

43 452 **2.4. Thermogravimetric methods**

44
45 453 Thermometric methods are also titrimetric methods that use the change of temperature
46
47 454 resulting from a chemical reaction to determine the end point of the titration. The
48
49 455 principle is the same as that for potentiometric auto-titration; the only difference is the
50
51 456 type of sensor (detector) usually thermistors are used. Vaughan and Swithenbank⁸¹
52
53 457 reported first considerable advances in determining the end point of the acid/base reaction
54
55 458 in non-aqueous medium. A novel titrimetric procedure has been reported for the
56
57
58
59
60

1
2
3 459 determination of FFA in edible oils using an automated thermometric titration with KOH
4
5 460 in isopropanol as titrant.⁸² The end point was indicated by the strongly exothermic base-
6
7 461 catalyzed reaction between acetone and chloroform. The procedure was accurate,
8
9 462 sensitive, easy to use, fast, and highly reproducible but did not get much attention.
10
11
12
13 463

14 464 **3. Conclusion**

15
16
17 465 The above described instrumental techniques proposed considerable merits over classical
18
19 466 titration methods in terms of speed, automation and reduction of costly as well as toxic
20
21 467 chemicals. Calorimetric methods have poor sensitivity and need frequent calibration.
22
23 468 Electrochemical methods require titrant standardization while accuracy and
24
25 469 reproducibility depends on the conditions of the electrodes. Optimization of several
26
27 470 parameters is also very essential. The discussion reflects that none of the methods
28
29 471 described provides specificity to FFA measurement as all are based on measuring total
30
31 472 acidity rather than FFA. Among the spectroscopic methods, FTIR methods have proved
32
33 473 to be more beneficial in terms of simplicity, economy, environment friendly nature and
34
35 474 speed of analysis, especially when using direct approach for the determination of FFA in
36
37 475 vegetable oils. However, selection of the method for FFA determination depends on the
38
39 476 availability of equipment, skilled worker, purpose of study and number of samples.
