

Analytical Methods

Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

Eight kinds of PAEs in five different brands of soybean milks were successfully determined using DLLME method coupled with GC-MS.

3 **Abstract**
4

5 31 Dispersive liquid–liquid microextraction (DLLME) was coupled with gas
6 32 chromatography and mass spectrometric detection for the determination of eight
7 33 phthalate acid esters (PAEs) in soybean milks. Parameters impacting on the extraction
8 34 efficiencies were optimized including organic solvents to extract PAEs from soybean
9 35 milks, salt concentrations and organic solvents for DLLME. Under the optimal
10 36 condition, limits of detection (LODs) and limits of quantification (LOQs) were in the
11 37 range of 0.57–0.79 and 1.90–2.63 ngg⁻¹, respectively. Linearities varied in the range
12 38 of 1–16000 ngg⁻¹ with the correlation coefficients of 0.9993–0.9998. The precisions
13 39 of the method were 2.9–3.2 in terms of RSD% based on triplicate measurements. The
14 40 preconcentration factors were in the range of 200-260. The recoveries of eight PAEs
15 41 were in the range from 79.0 to 110% at three spiked levels. The trace PAEs in five
16 42 different brands of soybean milks purchased from the market were determined
17 43 successfully.

61 Introduction

62 Soybean milk is a beverage made from soybeans and originated from China.
63 Many people consider soybean milk to be an everyday beverage because of its low
64 price, high content of proteins, antioxidants, unsaturated fatty acids, dietary fibers
65 and no cholesterol, etc. Soybean milk consumption has gained popularity in many
66 Asian countries and is also spreading to many other countries as well. Thus, soybean
67 milk packing is inevitably required for transportation and storage. Even though pure
68 polyvinyl chloride (PVC) is fairly unstable, the manifold applications are made
69 possible by the discovery of effective additives for the polymer. The most important
70 additives for the processing of PVC are phthalic acid esters (PAEs), which may be
71 incorporated into the polymer to improve flexibility, workability and general handling
72 properties.¹ Due to its particularly good polymer characteristics, PVC has an
73 enormously wide spectrum of applications for packaging liquid products, such as
74 beverages, edible oils, detergents, cosmetics and pharmaceuticals.

75 The source of PAEs in food is attributed mainly to (i) compounds which are
76 directly present in the aquifer as contaminants; (ii) external contamination from the
77 bottling plant and (iii) migration from containers, especially during storage.²⁻⁵ There
78 were several reports discussed the migration of PAEs from plastics into food.⁶⁻⁸ The
79 amount of PAEs in packaged foods depends on many factors including the
80 concentration of PAEs in the packaging material or printing ink, the storage period,
81 the storage temperature, the fat content in the food and the contact area.¹ In May,
82 2011, a scandal in Taiwan concerning food contamination with PAEs received
83 worldwide attention. Then, Public concern about PAEs in food is overwhelming, and
84 food contamination with PAEs has been regarding as a research priority to provide
85 urgently needed information for proper interventions in China.⁹ Toxicities of PAEs
86 could be cardiotoxicity, hepatotoxicity and nephrotoxicity.¹⁰

87 Soybean milks have complex sample matrices. They contain in general high
88 concentration of proteins, carbohydrates, fatty acids, dietary fibers and relative low
89 concentration of PAEs. An extraction process is necessary in the determination of
90 PAEs prior to performing chromatographic analysis. Extraction has two functions.
91 One is to enrich the low concentration of analytes to adequate level for detection or

1
2
3 92 quantification; the other is to isolate the desired analytes from sample matrices
4
5 93 which the instruments cannot detect directly. In principle, either liquid-liquid
6
7 94 extraction (LLE) or solid phase extraction (SPE) may be applied. However, none of
8
9 95 them is ideal in practice. LLE is a time consuming and tedious process, and requires a
10
11 96 large amount of expensive and high-purity organic solvents. After LLE, it usually
12
13 97 requires evaporation of the large volume solvents which are often flammable and
14
15 98 hazardous to human and environment. When subjected to SPE, a sample with
16
17 99 complex matrix, such as soybean milk, may plug into sorbent pores. Although
18
19 100 pre-filtrating the samples can avoid clogging and cleaning of SPE, it possibly leads to
20
21 101 the losses and contamination of the analytes.^{11, 12} In recent years, solid-phase
22
23 102 microextraction(SPME)¹³⁻¹⁵ and liquid-phase microextraction (LPME)^{16, 17} had been
24
25 103 developed as a solvent-minimized sample pretreatment procedure, in which the
26
27 104 analytes are extracted from aqueous or gaseous samples on to a solid porous hollow
28
29 105 fiber/membrane/fused silica fiber coated with a stationary phase. SPME has
30
31 106 important advantages over conventional extraction techniques, because it is solvent
32
33 107 free, fast, portable and easy to use. But SPME also suffers from some drawbacks such
34
35 108 as fiber fragile, limited lifetime and sample difficult to carryover, etc^{18, 19}. For LPME,
36
37 109 it overcomes the drawbacks of SPME and has the characteristics of simple setup, fast
38
39 110 processing and low-cost, etc., but still leaves some disadvantages: fast stirring would
40
41 111 tend to form air bubbles²⁰ and equilibrium cannot be attained within the time
42
43 112 required in most cases²¹. Recently, Assadi and co-workers²² have developed a novel
44
45 113 microextraction technique called dispersive liquid-liquid microextraction (DLLME).
46
47 114 DLLME is based on the appropriate mixture of a water-immiscible solvent (extractant)
48
49 115 and a water-miscible solvent (disperser), which is rapidly injected into the aqueous
50
51 116 sample that contains the analytes. After formation of a cloudy solution with a wide
52
53 117 contact surface between the sample and extracted agent, droplets of the
54
55 118 water-immiscible solvent containing the analytes are obtained. Through
56
57 119 centrifugation, the droplets of the water-immiscible solvent containing the analytes
58
59 120 can be collected in the sedimented phase and determined by chromatography or
60
121 spectrometry methods. Therefore, DLLME is fast, inexpensive, easy to operate with a
122
123 high enrichment factor and consumes low volume of organic solvent. Till now, DLLME
method has been applied for the extraction a large variety of organic compounds²³

1
2
3 124 and metal ions²⁴ from various kinds of matrices including PAEs in water²⁵, cow milk²⁶,
4 125 ²⁷ and recently in wine²⁸. However, no report has been made on the determination of
5
6 126 PAEs in soybean milks.

7
8 127 The goal of this work is to develop a reliable and rapid method for the
9
10 128 determination of PAEs in soybean milks. It was accomplished by employing DLLME
11
12 129 for sample pretreatment, gas chromatography for separation and mass spectrometry
13
14 130 for detection. Different experimental parameters were optimized to maximize
15
16 131 extraction efficiency. Under the optimal conditions, eight PAEs in five brands of
17
18 132 soybean milks from the local markets were determined successfully.

19 133 **Experimental section**

20 134 **Chemicals and solutions**

21
22 135 All chemicals mentioned in this section were obtained from Aladdin reagent
23
24 136 (Shanghai, China). Common phthalic acid esters (PAEs) included dimethyl phthalate
25
26 137 (DMP), diethyl phthalate (DEP), diisobutyl phthalate (DIBP), dibutyl phthalate (DBP),
27
28 138 dipentyl phthalate (DPP), dicyclohexyl phthalate (DCHP), di(2-ethylhexyl)phthalate
29
30 139 (DEHP) and dioctyl phthalate (DNOP). Carbon tetrachloride, 1,1,1-trichloroethane
31
32 140 (1,1,1-TCE), tetrachloroethylene and chlorobenzene were tested as the extractant in
33
34 141 DLLME. Methanol, ethanol, acetonitrile, acetone, isopropanol and tetrahydrofuran
35
36 142 were tested as the extraction solvent for the extraction of PAEs from soybean milks
37
38 143 and also as disperser in DLLME.

39 144 The stock solutions of eight PAEs were prepared in methanol at a concentration
40
41 145 of 0.4 mgg⁻¹. The stock solutions were stored at 4 °C in a refrigerator when not in
42
43 146 use. The working standard solutions were prepared by appropriately diluting the
44
45 147 stock solution of PAEs with ultrapure water as needed.

46 148 Five kinds of soybean milks in polyvinyl chloride (PVC) packing and produced by
47
48 149 different companies were purchased from local supermarkets (Shanghai, China).

49
50 150

51 151 **Instrumentation**

52
53 152 Analysis of PAEs was carried out on an Agilent 7890 gas chromatograph (GC)
54
55 153 with a 5975C Triple-Axis Detector (Agilent Technologies, CA, USA). The mass
56
57 154 spectrometric detection (MS) was operated at the electron impact (EI) mode (70

1
2
3 155 eV). The Agilent 7890 gas chromatograph was equipped with a split/splitless injector.
4
5 156 Helium (99.999%) was used as carrier gas at a constant flow rate of 1 mL/min. PAEs
6
7 157 were separated on a HP-5 capillary column (5% phenyl, 95% methyl siloxane, 30 m x
8
9 158 0.32 mm i.d. x 0.25 μm film thickness) (Agilent Technologies, CA, USA) with the
10
11 159 following oven temperature programming: initial temperature: 60 $^{\circ}\text{C}$ (held for 1 min)
12
13 160 and increased to 220 $^{\circ}\text{C}$ at a rate of 20 $^{\circ}\text{C}/\text{min}$ and held 220 $^{\circ}\text{C}$ for 1 min and then
14
15 161 from 220 to 280 $^{\circ}\text{C}$ at a rate of 5 $^{\circ}\text{C}/\text{min}$ and held at 290 $^{\circ}\text{C}$ for 4 min. Injector
16
17 162 temperature was set at 300 $^{\circ}\text{C}$. The EI ion source and interface temperature were
18
19 163 230 and 280 $^{\circ}\text{C}$, respectively. The solvent delay time was 8 min. All injections were in
20
21 164 splitless mode. The MS was operated on the total ion current (TIC) mode, scanning
22
23 165 from m/z 50 to 550 for identification purposes. To gain the highest possible sensitivity,
24
25 166 selective ion monitoring (SIM) mode was adopted for quantitative determination of
26
27 167 the PAEs. For each compound, the ion for quantitative analysis was based on
28
29 168 selection of the highest intensity mass peak. Peaks of m/z 163 and/or 149 were
30
31 169 scanned.

170 171 **Procedure of the extraction of PAEs from soybean milk**

172 All the extraction apparatus were glass-made, washed with methanol and dried
173 with air before use.

174 The extraction of PAEs could be divided into two steps. In the first step, 5 mL of
175 soybean milk was placed in a 10 mL glass tube. After spiking the standard solution of
176 PAEs, appropriate amount of sodium chloride was added. The glass tube was
177 manually shaken to dissolve the salt; then, 3 mL extraction organic solvent (used as
178 disperser in the next step) was added and centrifuged at a rate of 4000 rpm for 5 min,
179 and PAEs were extracted into the upper organic phase.

180 In the second step, 5 mL ultrapure water was placed into a 10 mL glass tube with
181 conical tip at the bottom, and 1 mL of the upper organic phase obtained in the first
182 step was added to the glass tube with conical tip; then, 40 μL carbon tetrachloride
183 was injected rapidly into this mixture, and centrifuged for 5 min at 4000 rpm to
184 obtain the sedimented phase; finally, 1 μL of the sedimented phase was removed and
185 injected into the GC system.

186 **Result and discussion**

187 In this two-step extraction process, optimization of the first step cannot be
188 performed independently from the second step. The organic solvent used as
189 extractant in the first step acts as the disperser in the second step. The solvent
190 properties, dispersive properties and volume would be more critical to the total
191 extraction efficiencies. Optimization of the two step processes is more complex than
192 the guidelines proposed for the optimization of a typical DLLME.

194 **Optimization of parameters in the extraction of PAEs from Soybean 195 milks**

196 **Selection of extraction solvent**

197 The extraction solvent was not only used as the extraction solvent which could
198 extract of PAEs from soybean milks but also as the disperser for the following DLLME
199 step. There are several requirements to select the extraction solvent: (i) the solvent is
200 capable of extraction of PAEs from the soybean milks, (ii) the solvent can be miscible
201 with the aqueous phase. The experiments were performed by adding different kinds
202 of organic solvents which were methanol, ethanol, acetonitrile (ACN), acetone,
203 isopropanol and tetrahydrofuran, and only ACN was observed to form a two phase
204 system. Thus, ACN was chosen as the extraction solvent for the following work.

205 **Study of ACN volume**

206 To evaluate the influence of ACN volume, 1, 2, 3, 4 and 5 mL of ACN were
207 separately added into the soybean milks containing 0.5 g NaCl, and two phases were
208 only observed for 3, 4 and 5 mL ACN added with the organic phase volumes of 1.2,
209 2.6, and 3.4 mL, respectively. As it can be seen from Fig.1, with the increase of ACN
210 volume, the PAEs were diluted into the ACN phase, and the peak areas decreased
211 relatively. The optimum volume for the extraction of PAEs from soya-bean milk
212 samples is 3 mL ACN, and 3 mL ACN was chosen as the optimum volume for the
213 extraction of PAEs from soya-bean milk samples.

Fig.1 Effect of ACN volume on the extraction efficiencies of PAEs from soybean milk. 5 mL soya-bean milk spiked with PAEs at the concentration of 30 ngg⁻¹. Centrifuge rate, 4000 rpm; centrifuge time, 5 min; volume of ACN in DLLME step, 0.8 mL; extraction solvent, carbon tetrachloride (100 µL); volume of ultrapure water in DLLME step, 5 mL; centrifuge rate in DLLME step, 4000 rpm; and centrifuge time in DLLME step, 5 min, separation system, GC, sample volume, 1 µL.

Optimization of salt concentration

Salt (NaCl) adding may have two effects on the extraction efficiencies of PAEs. One is that the salt addition can increase the amount of PAEs diffused into the extractant solvent to improve the formation of two-phase system; the other is that with salt addition increase the salting-out effect could reduce the solubility of the PAEs in water, and thus enhance the PAEs' concentration in the extract solvent phase. In the experiment, 0.3, 0.4, 0.5, 1.0, 1.5 and 2 g NaCl were added into soybean milk samples which were spiked with the PAEs at concentration of 30 ngg⁻¹, and the highest signal was obtained for 0.5 g NaCl as shown in Fig. 2.

Fig.2 Influence of salt concentration on the peak areas of PAEs. Extraction conditions: 5 mL soybean milk spiked with PAEs at concentration of 30 ngg⁻¹; volume of ACN in the first step, 3 mL; centrifuge rate, 4000 rpm; centrifuge time, 5 min; volume of ACN in the second step, 0.8 mL; extraction solvent, carbon tetrachloride (100 μ L); volume of ultrapurewater, 5mL; centrifuge rate, 4000 rpm; and centrifuge time, 5min; separation system, GC; sample volume, 1 μ L.

Optimization of parameters in DLLME process

Optimization of ACN volume in DLLME step

To obtain the optimal volume of ACN in DLLME step, various experiments were carried out by using different volumes of ACN in the range of 0.2–1.2 mL with an interval of 0.2 mL (shown in Fig.3). The results showed that the signals of the PAEs were increased initially with the volume of ACN up to 1.0 mL, but decreased thereafter. Therefore, 1.0 mL ACN was selected as the optimal disperser volume.

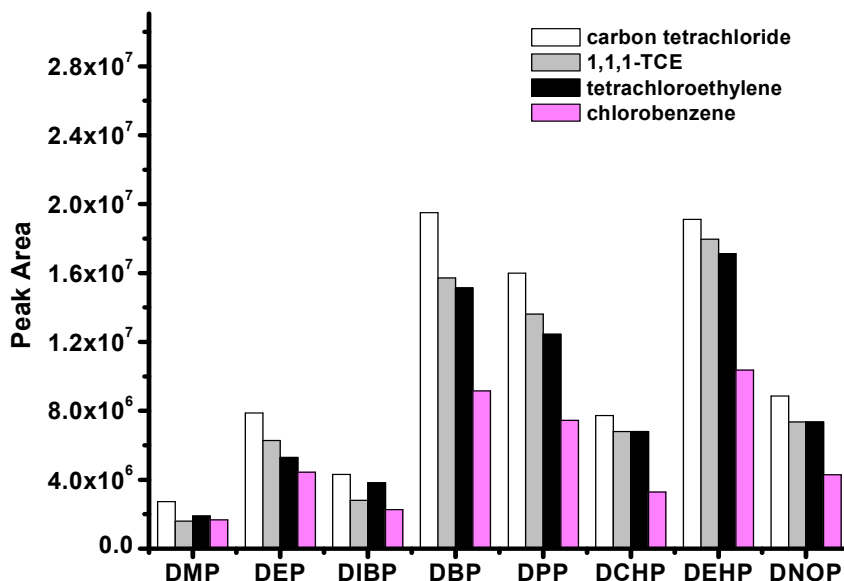

Fig.3 Influence of ACN volume on the extraction efficiency. Experimental conditions: Extraction condition: 5 mL soya-bean milk spiked with PAEs with the concentration of 30 ngg⁻¹. Salt, 0.5 g; volume of ACN in first step, 3 mL; centrifuge rate, 4000 rpm; centrifuge time, 5 min; extraction solvent, carbon tetrachloride (100 μ L); volume of ultrapurewater in DLLME step, 5 mL; centrifuge rate in DLLME step, 4000 rpm; and centrifuge time in DLLME step, 5 min; separation system, GC; sample volume, 1 μ L.

Selection of extraction solvent in DLLME process

The choice of an appropriate extraction solvent plays a key role for a DLLME process. When selecting an extraction solvent, there are five requirements to consider: (a) higher density than water, (b) good chromatographic behavior, (c) capable for extracting interested compounds, (d) low solubility in water and (e) able to form a two-phase system (cloudy solution) when injected into an aqueous solution in the presence of a dispersive solvent^{22, 25, 29}. In order to achieve the optimal extraction efficiency of PAEs from 1 mL ACN, 100 μ L carbon tetrachloride, 1,1,1-TCE, tetrachloroethylene and chlorobenzene were added, respectively. The results in Fig.4 revealed that CCl₄ presented the highest peak areas among the four extraction solvents tested. Therefore, CCl₄ was selected as the extraction solvent for this study.

265 **Fig.4** Effect of extraction solvent on the peak areas of PAEs in DLLME from soybean milk.

266 Experimental conditions: volume of ultrapurewater in DLLME step, 5 mL; volume of ACN in

267 DLLME step, 1 mL; centrifuge rate in DLLME step, 4000 rpm; centrifuge time in DLLME step,

268 5 min; separation system, GC; sample volume, 1 μ L.

269 **Optimization of extraction solvent volume in DLLME process**

270 Different volume of CCl_4 in the range of 20–100 μ L with an interval of 20 μ L was
271 tested in 5 mL ultrapurewater mixed with 1 mL upper organic phase of ACN obtained
272 from the first step. The results in Fig.5 showed that 40 μ L of extraction solvent
273 volume produced the highest peak signals, and 40 μ L was considered to be the
274 optimal solvent volume for the DLLME process.
275

Fig.5 Optimization volume of the extraction solvent. Extraction condition: 5 mL soybean milk spiked with PAEs at concentration of 30 ngg^{-1} . Salt, 0.5 g; volume of ACN in first step, 3 mL; centrifuge rate, 4000 rpm; centrifuge time, 5 min; volume of ACN in DLLME step, 1 mL; volume of ultrapurewater in DLLME step, 5 mL; extraction solvent, variable amount of carbon tetrachloride; centrifuge rate in DLLME step, 4000 rpm; centrifuge time, 5 min. Separation system, GC; sample volume, $1 \mu\text{L}$.

Validation of the method and analysis of the real samples

Validation of the method

To evaluate the proposed DLLME-GC-MS method, the linearity, correlation coefficients (r^2), relative standard deviations (RSDs), the limits of detection (LODs), limits of quantification (LOQs) and preconcentration factors (PFs) were determined. The results were summarized in Table 1. LODs and LOQs of the PAEs were found to be in the range of $0.57\text{--}0.79$ and $1.90\text{--}2.63 \text{ ngg}^{-1}$, respectively. The former were determined based on the signal-to-noise ratio (S/N) of 3 and the latter to be 10. Linearities varied in the range of $1\text{--}16000 \text{ ngg}^{-1}$ with the correlation coefficients of $0.9993\text{--}0.9998$. The precisions of the method were $2.9\text{--}3.2$ in terms of RSD based on triplicate measurements. Furthermore, the preconcentration factors (PFs) were from 200 to 260. For the definition and calculation of PFs, the information could be found in an early report.²³

298 **Table-1:** Evaluation on analytical performance of DLLME and GC/MS determination of the
 299 selected PAEs.

Linear equation of analytes		R ²	LOD (ngg ⁻¹)	LOQ (ngg ⁻¹)	RSD (%)	PF (fold)
DMP	Y=6.52x10 ⁵ X+2.72x10 ³	0.9994	0.62	2.07	3.2	241

300

301 **Analysis of the real samples**

302 The proposed method was applied to determine the PAEs in five different
 303 brands of soybean milks, which were bought from local markets. The DLLME was
 304 employed for the sample pretreatment and the GC-MS was used for the separation
 305 and detection of the PAEs in the real samples. The results in Table 2 showed that
 306 trace PAEs contaminations were detected in all five samples. A typical GC-MS
 307 chromatogram of soybean milk and mass spectra of DCHP with m/z 149 and 163 was
 308 showed in Fig.6. To investigate the effect of sample matrix on the accuracy of the
 309 determination, the recoveries were measured by spiking three different
 310 concentrations of PAEs into the samples. The recoveries were from 79.0 to 110%
 311 (Table 3) which demonstrated the feasibility of DLLME-GC-MS for the determination
 312 of PAEs in soybean milks.

313

354 355 **Comparison of DLLME with other methods**

356 Table 4 indicates the values of LODs LR, RSD, the extraction time and the sample
357 volumes of the DLLME and other methods for the extraction and determination of
358 PAEs from the similar matrix. From the table, we can see that the present DLLME
359 method offers some advantages of lower LODs, wider linear range, simple extraction
360 procedure, and less-time consuming sample preparation. It is also revealed that the
361 DLLME method was a sensitive, rapid and reproducible technique that could be used
362 for extraction, preconcentration and determination of PAEs in a complex matrix such
363 as soy-bean milk.

372

373 Table-4 Comparison of DLLME with other methods for determination of PAEs.

Method	LOD(ngg^{-1})	LR(ngg^{-1})	RSD(%)	Extraction time(min)	Sample volume(mL)	Ref.
SPE-LC-MS/MS ^(a)	0.2-0.6	1-1200	3-5	30	10	30
LLE-LC-MS ^(b)	4-9	20-900	1-2	20	100	31
LLE-LC-MS/MS ^(c)	0.01-0.5	--	2-6	100	3	32
DLLME-GC-MS	0.57-0.79	1-16000	2.9-3.2	15	5	this method

377

378

379 **Conclusion**

380 In this study, dispersive liquid–liquid microextraction (DLLME) was coupled with
 381 GC-MS for the determination of phthalate acid esters (PAEs) in soybean milks.
 382 Acetonitrile was first used to extract PAEs from soybean milks and then facilitated to
 383 use carbon tetrachloride in DLLME. The sedimented organic phase could be
 384 subjected to GC-MS for the separation and the detection. It was observed that all
 385 trace PAEs contaminations were present in all the five samples. By using of the
 386 DLLME, the preconcentration factors for the PAEs were in the range of 200-260 folds.
