Accepted Manuscript

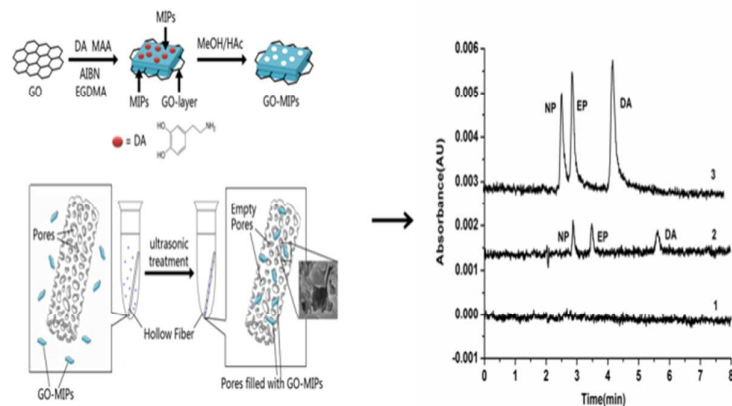

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

A novel solid phase microextraction method with selectivity: Hollow fiber supported graphene oxide-molecularly imprinted polymers for determination of dopamine by HPLC-PDA

15 **Abstract:** Molecularly imprinted polymers (MIPs) of dopamine (DA) were
16 constructed on the surface of graphene oxide (GO), and attached inside the
17 pores of hollow fibers (HF) for the solid-phase microextraction (SPME) of
18 DA. Scanning electron microscopy, thermo gravimetric analysis and Raman
19 spectroscopy indicated that GO-MIPs composites were successfully
20 synthesized and modified in the pores of HF via ultrasonication. Compared
21 with common HF and HF modified with non-imprinted polymers
22 (GO-NIPs/HF) using the same SPME procedures, the GO-MIPs/HF
23 composite showed the best efficiency for the extraction of DA. The
24 selectivity of GO-MIPs/HF was investigated based on the selectivity factor
25 (*F*) using epinephrine and norepinephrine as the structural analogues of DA.
26 The linear range of dopamine was 1.05×10^{-3} - 5.27×10^{-3} $\mu\text{mol/mL}$ using this
27 process with a detection limit of 2.64×10^{-4} $\mu\text{mol/mL}$. The extraction
28 procedure based on GO-MIPs/HF was successfully used for the
29 determination of DA in human serum and its hydrochloride injection,
30 showing average recoveries of 83-96%. GO-MIPs/HF was a good carrier for
31 the selective adsorption of DA, and shows promise for the preconcentration
32 of DA in real samples.

24 **1 Introduction**

25 Since their discovery in 2004, graphene and graphene-based materials have
26 received tremendous attention because of their unique nanostructures and
27 extraordinary properties, such as their large surface areas and good conductivities.
28 These properties make graphene-based materials promising candidates for
29 applications in biochemical and chemical sensing,^{1, 2} sample preparation³⁻⁵ and
30 biomedical applications.⁶⁻⁸ Because of their large surface areas, graphene and
31 graphene-based materials provide ideal platforms for sample pretreatment via
32 solid-phase extraction (SPE) and solid-phase microextraction (SPME).^{4, 5} Despite
33 their outstanding efficiency for the enrichment and cleanup of targets, graphene-based
34 materials show low selectivity for the extraction of target analytes. To overcome this
35 disadvantage, functional graphene-based composites have been designed using
36 molecular imprinting techniques.

37 Molecular imprinting is a promising method for the preparation of extraction
38 materials (termed molecularly imprinted polymers, MIPs) with high selectivity. The
39 synthesis of MIPs involves the formation of a complex of a target molecule with
40 functional monomers using covalent or non-covalent interactions, followed by a
41 polymerization reaction with a cross-linking agent. Then the imprinted
42 molecules are removed from the polymer. The advantages of MIPs, including
43 stability, ease of preparation, and low cost, have resulted in wide use in chemical
44 sensor and sample preparation.⁹⁻¹³ Recently, a novel molecular imprinting
45 technique on the surface of nanomaterial was applied for the preparation of

1
2
3
4 46 surface MIPs with favorable selectivity. For example, surface MIPs were
5
6 47 synthesized on the surface of carbon nanotubes (CNTs)¹⁴⁻¹⁸ and graphene,¹⁹⁻²⁷
7
8
9 48 and most of these composites were utilized to detect the target analytes. A
10
11 49 novel composite of SiO₂-coated graphene oxide and molecularly imprinted
12
13 50 polymers was synthesized for the electrochemical sensing of dopamine by Zeng
14
15
16 51 *et al.*¹⁹ However, only a few studies concern sample pretreatment using MIPs
17
18
19 52 based on graphene oxide (GO).

20
21 53 Although graphene-based MIPs have a higher selectivity than traditional
22
23 54 MIPs, some interference remains when studying large molecules in biological
24
25 55 samples even though MIPs were designed using small molecules as the
26
27
28 56 template. Based on liquid-phase microextraction using hollow fiber membranes
29
30
31 57 (HF-LPME) for sample preparation,²⁸ the large molecules are prevented from
32
33 58 entering the small pores of the fibers. To improve the extraction efficiency of
34
35
36 59 HF-LPME, CNTs and graphene-reinforced hollow fiber microporous
37
38
39 60 membrane liquid phase microextraction have been used.²⁹⁻³¹

40
41 61 Herein, we proposed a novel imprinting route based on GO to prepare
42
43 62 GO-MIP composites, which were attached to HF using ultrasonication.
44
45 63 Dopamine (DA), an important neurotransmitter, was used as the template
46
47
48 64 molecule in this work. This GO-MIPs/HF composite was used as the sorbent in
49
50
51 65 SPME for the extraction of DA from real samples with satisfactory selectivity,
52
53
54 66 and was analyzed using HPLC method.

68 2 Experimental

69 2.1 Reagents and material

70 Dopamine (DA), norepinephrine (NP), epinephrine (EP), ethylene glycol
71 dimethacrylate (EGDMA) and methacrylic acid (MAA) were obtained from
72 Sigma-Aldrich (Shanghai, China). Graphene oxide (GO) was purchased from
73 XFNano Materials Tech. Co., Ltd. (Nanjing, China). 2, 2-Azobisisobutyronitrile
74 (AIBN) was supplied by Aladdin Reagent Co., Ltd. (Shanghai, China).
75 Methylbenzene (MB), *N, N*-dimethyl formamide (DMF), acetic acid and acetone
76 were purchased from Beijing Chemical Plant (Beijing, China). Chromatographic
77 grade methanol was purchased from Merck Co. (Darmstadt, Germany). Accurel
78 Q3/2 Polypropylene hollow fiber membranes (200- μm wall thickness, 600- μm
79 i.d., 0.2- μm average pore size) were provided by Membrane (Wuppertal,
80 Germany). Deionized water (18.2 M Ω) was purified using a Milli-Q system
81 (Billerica, USA). All other reagents were of analytical grade and used without
82 further purification. All solutions were filtered through 0.22 μm pore size filters
83 (Tianjin, China).

84 The dopamine hydrochloride injections used in this work were purchased
85 from a local drug store, and stored at 4 °C. Blood samples were collected from
86 healthy volunteers in the morning. Three milliliters of blood was allowed to clot
87 at room temperature for at least 1 hour, and then centrifuged (4,000 rpm) for 20
88 min at 4 °C. Then, the serum was collected, aliquoted, and stored at -80 °C until
89 further processing.

8
9
10 92 All separations were performed on a high performance liquid chromatography
11
12 93 (HPLC, Waters 2695, Waters Technologies, USA) with a photodiode array
13
14 94 detector (PDA, Waters 2998, Waters Technologies, USA) and the detection
15
16 95 wavelength was set to 280 nm. An RP 18 column (5 μm , 150 mm \times 4.6 mm i.d.)
17
18 96 was used for the separation column. The data were acquired using Empower
19
20 97 software (Waters Technologies, USA). The HPLC-PDA assay was performed
21
22 98 using an 8-min isocratic elution with a flow rate of 0.8 mL/min. The volume of
23
24 99 each injection was 5.0 μL . The mobile phase consisted of 100 mM of ammonium
25
26 100 acetate (pH 5.0), acetonitrile and water (10:2:88). The mobile phase was filtered
27
28 101 through a 0.22- μm pore size filter and degassed for 30 min before use.

29
30
31
32
33
34
35 102 Scanning electron microscope (SEM) images were taken using an S-4800
36
37 103 field scanning electron microscope (Hitachi, Japan) operating at 15 kV. Raman
38
39 104 spectra were collected using a Raman spectrometer (Renishaw, UK) with a
40
41 105 633-nm excitation wavelength. Thermo gravimetric analysis (TGA) was
42
43 106 conducted on an HCT-1 instrument (Beijing Henven Scientific Instrument
44
45 107 Factory, Beijing) from room temperature to 800 $^{\circ}\text{C}$ with a heating rate of 10
46
47 108 $^{\circ}\text{C}/\text{min}$ under nitrogen flow.

7 111 **2.3 Preparation of stock solutions and real samples**8
9
10 112 Stock solutions of DA, NP and EP were prepared in water and stored at 4 °C
11
12 113 until use. All working solutions of different concentrations were freshly prepared
13
14 114 through appropriate dilution of the stock solution with deionized water. The
15
16 115 dopamine hydrochloride injections were filtered through a 0.22- μ m pore filter
17
18 116 before use, without any other pretreatment.19
20
21
22 117 The frozen serum samples were defrosted on ice and centrifuged (10, 000
23
24 118 rpm) for 2 min at 4 °C. Then, 0.5 mL of ACN was added to the serum (100 μ L) to
25
26 119 precipitate the proteins. The sample solution was centrifuged for 5 min to
27
28 120 remove the precipitates. The supernatant of the serum sample was purged with
29
30 121 N₂ until dryness. The analytes in the residuals were redissolved in 1.5 mL of
31
32 122 deionized water via ultrasonication for 10 min. After filtration through a
33
34 123 0.22- μ m membrane filter, the sample solution was used for SPME.35

42
43 125 **2.4 Synthesis of GO-MIPs**44
45
46 126 First, 0.038 g of DA (template molecule) was added to a solution of 8.0 mL of
47
48 127 DMF, 2.0 mL of MB and 0.17 mL of MAA. This mixture was ultrasonicated for 1
49
50 128 hrs. Then, 25 mL of a GO dispersion (4 mg/mL), 0.06 g of AIBN, and 0.38 mL of
51
52 129 EGDMA were added to the mixture followed by ultrasonication for 15 min.
53
54
55
56 130 Next, the temperature was held at 65 °C for 24 hrs to allow polymerization.
57
58
59
60

1
2
3
4 131 Polymerization occurred via non-covalent binding, such as π - π stacking. There
5
6 132 was effective charge transfer between the monomers-template and graphene
7
8 133 oxide, which agreed with the Raman spectral analysis.²¹ Next, the composites
9
10 134 were collected via centrifugation and washed twice with methanol to remove
11
12 135 residual impurities. The imprinted template of DA was removed from the
13
14 136 polymers using methanol and acetic acid (9:1, v/v) until no DA was detected in
15
16 137 the eluent. Afterwards, the MIPs were dried under nitrogen gas. Non-imprinted
17
18 138 polymers (NIPs) were synthesized using the same procedure without adding DA
19
20 139 as the template during the polymerization process.

29 141 **2.5 Procedure for GO-MIPs/HF preparation**

30
31
32 142 A schematic diagram of the preparation of GO-MIPs/HF is shown in **Fig. 1**.
33
34 143 Polypropylene HF was cut into 2-cm segments, and these segments were
35
36 144 ultrasonicated in an acetone solution for 3 min to remove any contaminants from
37
38 145 the fiber segments. Next, the HF segments were removed from the acetone
39
40 146 solution, and the remaining acetone was allowed to completely evaporated. Each
41
42 147 segment was then immersed into 0.60 mL of GO-MIPs dispersion (2 mg/mL in
43
44 148 DMF) and ultrasonicated for 2 hrs. After ultrasonication, the segments were
45
46 149 washed for three times with water to remove the excess composites.
47
48
49
50 150 GO-NIPs/HF was prepared using GO-NIP composites using the same procedure
51
52
53
54
55 151 as that for the GO-MIPs/HF.
56
57
58
59
60

152 **Fig. 1** A schematic illustration of the preparation of GO-MIPs/HF and the SEM
 153 image of GO-MIPs/HF ($\times 10\,000$).

155 2.6 Solid-phase microextraction

156 The extraction and preconcentration procedures for the target analytes were as
 157 follows: 1.5 mL of a DA solution or pretreated sample solution was placed into a
 158 centrifuge tube, and a GO-MIPs/HF sample was then immersed in the solution. The
 159 solution was vortexed for 20 min on a rotator with a speed of 1,000 rpm. After
 160 extraction, the GO-MIPs/HF was removed and analytes were desorbed using 50 μ L of
 161 a mixture methanol and acetic acid (9:1, v/v).

162

163

164 **3 Results and discussion**165 **3.1 Characterization of the GO/MIPs and GO/MIPs-HF**

166 The SEM images of the GO, GO-NIPs and GO-MIPs are shown in **Fig. 2a-2c**. The
167 GO sheets showed thin, wrinkled, smooth surfaces and layered structures (**Fig. 2a**)
168 which are typical characteristics of GO. After polymerization, the surface of the
169 GO-NIPs and GO-MIPs became rough and cross-linked, and new shapes appeared.
170 Compared with the GO-NIP composites, GO-MIP composites showed a high degree
171 of cross-linking because the target molecules provided sites for the polymerization.
172 These results indicated that the GO-MIPs were successfully synthesized. The SEM
173 image in **Fig. 1** shows that a number of holes on the wall of HF were filled with
174 GO-MIP composites.

175 **Fig. 2** SEM images of GO (a), GO-NIPs (b), GO-MIPs (c). Conditions: acceleration
176 voltage, 15 kV; magnification, $\times 50\,000$.

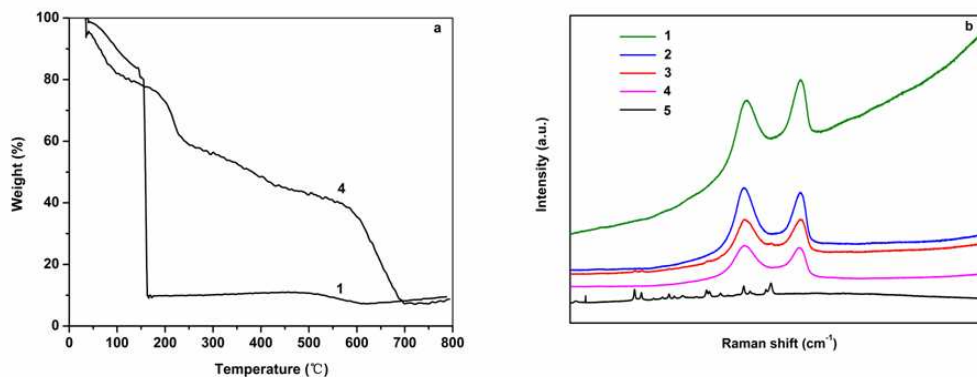

177

178 **Fig. 3a** shows TGA weight loss curves for the GO and GO-MIPs, respectively. As
179 shown in **Fig. 3a**, GO was not thermally stable. The weight of the GO declined

1
2
3
4 180 sharply between 100 °C and 200 °C due to the removal of functional groups (-OH and
5
6 181 -COOH).³² After the polymerization reaction, the MIP composites appeared to be
7
8
9 182 effective at enhancing the thermal stability of GO sheets. A weight loss of 30% was
10
11 183 observed between 550 °C and 700 °C, which might be due to decomposition of the
12
13 184 polymer.²² Based on the difference in thermal stability between GO and GO-MIPs,
14
15 185 the TGA measurements indicated that the MIPs were successfully adhered onto the
16
17
18 186 GO surface.

19
20
21 187 Raman spectroscopy is one of the most widely used techniques to characterize the
22
23 188 structures and electronic states of carbon materials, including CNTs, graphene and
24
25 189 GO. The Raman spectra of the GO, GO-NIPs, GO-MIPs, HF and GO-MIPs/HF are
26
27
28 190 shown in **Fig. 3b**. The D band and G band represent disordered sp³ carbon and
29
30 191 ordered sp² crystalline graphite-like structures, respectively.²¹ The Raman shifts of
31
32 192 the GO-NIPs and GO-MIPs were different from the Raman shifts of GO due to the
33
34 193 charge transfer between the GO and the other components in the GO-MIPs and
35
36 194 GO-NIPs. The I_(D)/I_(G) ratios of the GO-NIPs and GO-MIPs were higher than GO
37
38 195 (0.906), which indicated increased disorder in the composites due to the polymer
39
40 196 coating on the surface of GO, which resulted in increased disorder in the polymeric
41
42 197 compounds³³. Meanwhile, the peak intensities of the GO-NIPs were lower than the
43
44 198 peak intensities of the GO-MIPs, possibly because a greater number of carbon atoms
45
46 199 participated in the polymerization during the synthesis of the GO-MIPs. The HF
47
48 200 exhibited no absorption peaks near the Raman shift of the GO-MIPs, while the G
49
50 201 band and D band appeared in the GO-MIPs/HF spectra after decoration. The Raman
51
52
53
54
55
56
57
58
59
60

202 spectra indicated that the GO-MIPs composites were synthesized and combined with
203 HF.

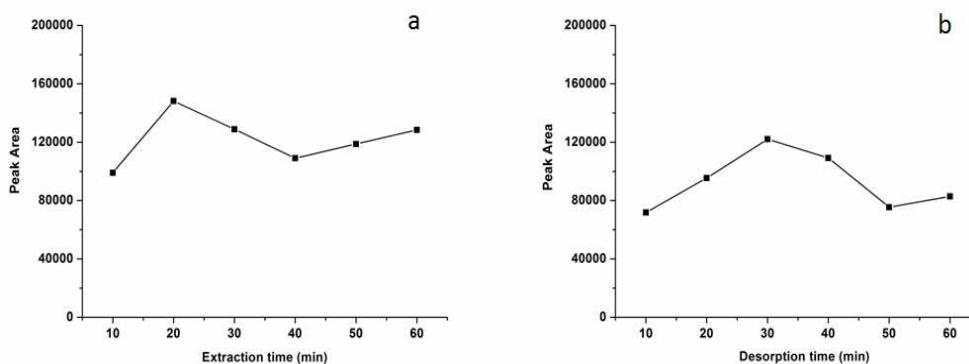

204 **Fig. 3** The TGA curves and Raman spectra of the following compounds. (1) GO (D
205 band: 1346, G band: 1601); (2) GO-NIPs (D band: 1335, G band: 1599); (3)
206 GO-MIPs/HF (D band: 1331, G band: 1601); (4) GO-MIPs (D band: 1331, G band:
207 1594); (5) HF.

208

209 3.2 Optimization of SPME conditions

210 In the SPME method, maximum extraction of analytes is achieved at
211 equilibrium. To obtain the highest extraction efficiency of DA, the extraction
212 times from 10 to 60 min were investigated with a desorption time of 30 min. As
213 shown in **Fig. 4a**, the peak areas of the target analytes increased from 10 to 20
214 min, While the peak areas decreased after 20 min. This phenomenon might result
215 from analyte loss caused by the prolonged extraction time which would be
216 disadvantageous for the contact between the analyte and the MIPs. Therefore,
217 20 min was selected as the optimal extraction time for the GO-MIPs/HF SPME
218 method.

1
2
3
4 219 In this work, the extracted compounds were desorbed from the GO-MIPs/HF
5
6 220 using 50 μL of methanol and acetic acid (9:1, v/v) and vortexing; the desorption
7
8
9 221 time exerted a significant influence on the signal intensity of the extracted
10
11 222 analytes. The effect of desorption times from 10-60 min on GO-MIPs/HF SPME
12
13 223 was investigated, and the highest peak area of DA was achieved at 30 min (as
14
15 224 shown in **Fig. 4b**). The desorption was incomplete when a shorter desorption
16
17 225 time was used, and the peak area of DA decreased when the desorption was
18
19 226 performed for longer than 30 min, which may have resulted because the
20
21 227 desorbed analytes could be reabsorbed by the GO-MIPs/HF. Therefore, 30 min
22
23 228 was chosen as the desorption time for the SPME method.

229 **Fig. 4** Effect of extraction time (a) and desorption time (b).

231 3.3 Comparison between GO-MIPs/HF and HF on the extraction of DA,

232 NP and EP

233 In this work, the unmodified HF was used to extract a mixed solution using
234 the same procedure as the GO-MIPs/HF SPME, and the results are shown in
235 **Fig.5**. As shown in the figure, the three target analytes (DA: $5.27 \times 10^{-3} \mu\text{mol/mL}$;

NP: 4.86×10^{-3} $\mu\text{mol/mL}$; EP: 4.55×10^{-3} $\mu\text{mol/mL}$) were slightly, but clearly, detected without any preparation (curve 2), but cannot be detected using the unmodified HF and the proposed SPME procedure (curve 1). After the GO-MIPs/HF SPME procedures, the peak area increased apparently and the GO-MIPs exhibited its advantages in the extraction process (curve 3). Compared with the unmodified HF, the presence of GO-MIPs composites increased the π - π interactions between the benzene rings of the analyte and the ring structures in the graphene oxide, which provided the specific adsorption sites for the cavities.

Fig. 5 Chromatograms of a mixed solution of DA, NP and EP without any pretreatment (2), treated with unmodified HF (1), and treated with GO-MIPs/HF (3).

3.4 Selectivity of GO-MIPs/HF

To evaluate the selectivity of GO-MIPs/HF towards the target molecule DA, NP and EP (DA: 5.27×10^{-3} $\mu\text{mol/mL}$; NP: 4.86×10^{-3} $\mu\text{mol/mL}$; EP: 4.55×10^{-3} $\mu\text{mol/mL}$) were chosen for the comparison due to their activities, structural

1
2
3
4 252 similarities and the coexistence with DA in real samples. The selectivity was
5
6 253 calculated using the selectivity factor (F):
7
8

$$F = \frac{A_M}{A_N}$$

9
10
11
12 254 where A_M and A_N are the peak areas using GO-MIPs/HF treatment and
13
14 255 GO-NIPs/HF treatments, respectively. Of three batches, GO-MIPs/HF exhibited
15
16 256 the highest F for DA with an average value of 4.87 with RSD 6.2% ($n=3$),
17
18 257 whereas the average F values of EP and NP were 1.42 (RSD11.4%, $n=3$) and
19
20 258 1.99 (RSD5.3%, $n=3$), respectively. For the comparison of selectivity of
21
22 259 GO-MIPs/HF on these analytes, t -test on the selectivity factors was investigated.
23
24 260 Between DA and NP with the confidence level at 90%, the value of t was 15.28,
25
26 261 which was higher than 2.13 ($t_{0.10, 4}$ of the standard values). So the selectivity
27
28 262 between NP and EP had a significant difference. Between NP and EP with the
29
30 263 confidence lever at 90%, the value of t was 0.70, which was lower than 2.13
31
32 264 ($t_{0.10, 4}$ of the standard values). So the selectivity values between NP and EP had
33
34 265 no significant difference. It meant that GO-MIPs/HF had showed a stable
35
36 266 adsorption and an greater binding capacity for DA. This increased capacity
37
38 267 maybe attributable to the perfect fit of the shapes of the cavities in the polymers
39
40 268 for the unique molecular structure of DA. Thus, EP and NP cannot be adsorbed
41
42 269 into the imprinted cavities via specific binding. Therefore, the GO-MIPs/HF
43
44 270 showed good selectivity for the template molecule and its analogues.
45

271

272 3.5 Evaluation of analytical performance

273 Certain performance parameters including the relative standard deviations
274 (RSDs), linearity, limit of detection (LOD) and limit of quantification (LOQ)
275 were evaluated for the extraction of DA under the optimum extraction
276 conditions. The precision of the developed method was assessed by performing
277 intra-day and inter-day assays. The intra-day precision was measured for six
278 parallel procedures in one day and the RSD of the peak area was 3.2%. The
279 inter-day precision was calculated on three consecutive days and showed an
280 RSD of 4.3%. These data indicated that the proposed method was stable for the
281 extraction of DA. The LOD of DA was 2.64×10^{-4} $\mu\text{mol/mL}$, and the LOQ was
282 1.05×10^{-3} $\mu\text{mol/mL}$. Calibration standard solutions in the range of
283 1.05×10^{-3} - 5.27×10^{-3} $\mu\text{mol/mL}$ were extracted using the GO-MIPs/HF and
284 GO-NIPs/HF SPME methods and analyzed using HPLC. The GO-MIPs
285 composites have a better adsorption than GO-NIPs composites. According the
286 results of GO-MIPs/HF SPME, The linear regression equation for DA was
287 $y = 2.59 \times 10^7 x + 3478$ with a correlation coefficient of 0.998. As shown in **Fig. 6**,
288 as the concentrations increase beyond the linear range, the peak areas rise slowly.
289 The material has clearly achieved saturation.

290

291 **Fig. 6** Peak areas of different concentrations of DA and the linearity curve
292 (inset).

293

294 3.6 Real samples

295 Real samples were analyzed using the standard addition method. To fit into the
296 linear ranges, the DA standard solutions with different concentration levels
297 ($1.32 \times 10^{-3} \mu\text{mol/mL}$, $2.64 \times 10^{-3} \mu\text{mol/mL}$ and $3.96 \times 10^{-3} \mu\text{mol/mL}$) were added
298 into the serum and the DA hydrochloride injection. The results of the recovery
299 test were shown in **Table 1** and **Table 2**. As shown in the **Table 1-2**, the recovery
300 of the added DA had the potential to be quantitative and ranged between
301 83%-96%. The RSD values were 4.4%-5.9% for serum samples and 5.4%-7.7%
302 for DA hydrochloride injection, respectively.

303

304 **Table 1** Recovery results of DA in serum samples by using the SPME method
 305 with GO-MIPs/HF ($n=5$).

Sample No.	Found ($\mu\text{mol/mL}$)	Spiked ($\mu\text{mol/mL}$)	Total Found ($\mu\text{mol/mL}$) [*]	Recovery	RSD
1	-	1.32×10^{-3}	$(1.19 \pm 0.12) \times 10^{-3}$	90%	5.9%
2	-	2.64×10^{-3}	$(2.20 \pm 0.16) \times 10^{-3}$	83 %	4.4%
3	-	3.96×10^{-3}	$(3.55 \pm 0.32) \times 10^{-3}$	89 %	5.5%

306 ^{*}Average ± 1.68 \times standard deviation with the confidence level at 90%

308 **Table 2** Recovery results of DA in DA hydrochloride injection by using the
 309 SPME method with GO-MIPs/HF ($n=5$).

Sample No.	Found ($\mu\text{mol/mL}$) [*]	Spiked ($\mu\text{mol/mL}$)	Total Found ($\mu\text{mol/mL}$) [*]	Recovery	RSD
1	$(1.38 \pm 0.07) \times 10^{-3}$	1.32×10^{-3}	$(2.65 \pm 0.20) \times 10^{-3}$	96%	7.7%
2	$(1.35 \pm 0.08) \times 10^{-3}$	2.64×10^{-3}	$(3.88 \pm 0.22) \times 10^{-3}$	96%	5.4%
3	$(1.32 \pm 0.12) \times 10^{-3}$	3.96×10^{-3}	$(5.01 \pm 0.39) \times 10^{-3}$	93%	6.7%

310 ^{*}Average ± 1.68 \times standard deviation with the confidence level at 90%

312 3.7 Comparison of the proposed method with previous reports

313 As compared with the liquid-phase microextraction with hollow fiber,³⁴ the
 314 procedure based GO-MIPs/HF SPME was simple and eco-friendly without
 315 1-octanol and the required equipment was inexpensive. Compared with

1
2
3
4 316 graphene reinforced hollow fiber liquid-phase microextraction,³¹ the proposed
5
6 317 GO-MIPs/HF SPME method showed satisfactory selectivity in the presence of
7
8
9 318 coexist substances. The LOD, RSD and recoveries of the GO-MIPs/HF SPME
10
11 319 method were comparable with imprinted electrochemical sensor for dopamine.
12
13 320 ^{14, 15, 19} What's more, the proposed method showed better selectivity results than
14
15
16 321 the electrochemical sensor. The developed SPME method was suitable for
17
18
19 322 complex matrix samples without additional clean-up processes. These results
20
21 323 show that the GO-MIPs/HF method is a sensitive, rapid and easy to handle
22
23
24 324 technique for the pretreatment of target analyte from complex samples.
25
26
27
28

29 326 **4 Conclusions**

30
31 327 Composites of GO-MIPs were successfully synthesized for DA extraction
32
33 328 using a novel imprinting route and an SPME method based on GO-MIPs/HF
34
35
36 329 combined with HPLC was developed for the determination of DA in real
37
38
39 330 samples. The proposed method shows a good selectivity for the extraction and
40
41 331 enrichment of DA from real samples because of the combination of large
42
43
44 332 surface area of graphene oxide, selectivity of MIPs and blocking interference of
45
46
47 333 biomacromolecular by hollow fiber. Under the optimized conditions, this
48
49 334 method demonstrated a low LOD and satisfactory repeatability. However, it
50
51 335 also exhibited certain disadvantages, such as a narrow linear range, because the
52
53
54 336 material reached maximum adsorption. The presence of GO-MIPs on the
55
56
57 337 hollow fiber wall increased the effective surface area and the proposed method
58
59
60

1
2
3
4 338 may be a powerful and promising sample preparation technique for

5
6 339 catecholamines in drugs and biological matrices.
