5  
6 **Abstract**

7 A simple and effective method based on magnetic solid-phase extraction combined  
8 with high performance liquid chromatography was used for the determination of  
9 hindered phenolic antioxidants in plastic packaging injections. The extraction and  
10 cleanup via Fe<sub>3</sub>O<sub>4</sub>@CTAB magnetic adsorbent dispersion in injections followed by  
11 magnetic isolation and desorption of the analytes using acetonitrile. The cationic  
12 surfactant cetyltrimethylammonium bromide (CTAB) coated on the surface of Fe<sub>3</sub>O<sub>4</sub>  
13 nanoparticles adsorbent was synthesized. Main parameters affecting the adsorption  
14 recoveries were evaluated and optimized, including the amount of surfactant and  
15 adsorbent, pH, ionic strength, desorption conditions, and sample volume. Under the  
16 optimum conditions, the method was successfully applied to the determination of  
17 hindered phenolic antioxidants in plastic packaging injections. Low limits of detection  
18 (LODs) of 0.14 and 0.15 µg mL<sup>-1</sup> and limits of quantification (LOQs) of 0.45 and  
19 0.50 µg mL<sup>-1</sup> were achieved. The mean recoveries were in the range from 85.0 to  
20 93.5% at 5, 10, and 20 µg mL<sup>-1</sup> spiked levels, and the relative standard deviations  
21 (RSDs) were in the range from 1.16 to 2.81%.

22 **Key words:** magnetic solid phase extraction; hindered phenolic antioxidants;  
23 injections

## 1. Introduction

Polypropylene (PP), a kind of the plastic materials is widely used for food packaging, lab equipments and automotive parts, due to its excellent mechanical properties, low cost, and superior processibility. However, PP is likely to be degraded when processing at high temperature or for prolonged use under unfavorable conditions, in the case of light, heat, and chemical agents. Thus, a large number of organic and inorganic additives were added to the PP plastic to improve its stability and durability during manufacture, transport and storage. The additives include antioxidants stabilizers, lubricants, softeners and coloring agents <sup>1</sup>.

Antioxidants can be classified as primary and secondary based on their action mechanisms. Radical scavengers, one of the well known primary antioxidants, inhibit oxidation by donating a hydrogen atom, thus competing with the polymer in the formation of peroxy radicals. Hindered phenolic antioxidants are another kind of effective primary antioxidants most used in industry, which have good pollution-free and non-discoloring properties compared with the toxicity and discoloration of aromatic amine antioxidants <sup>2-4</sup>. These antioxidants can improve stability of plastics, but they can also migrate from plastics into its content and contaminate it after a long time contact. The related problem of public safety attracts much attention, especially a variety of injections are also stored in this plastic bottles nowadays.

It is obvious that studies on the migration mechanism and migration levels of these additives are very important for the quality control of injections. The sample pretreatment is a significant step because of the trace content of antioxidants in plastic. Recently, some pretreatment techniques were used for sample preparation of additives in plastics, such as liquid-liquid extraction (LLE) <sup>5,6</sup>, solid-phase extraction (SPE) <sup>7-9</sup>, solid-phase microextraction (SPME) <sup>10-12</sup>, liquid-phase microextraction (LPME) <sup>13</sup>, and so on. The aforementioned methods have some limitations to some degree, such as time-consuming, or require large volumes of solvents. Therefore, establishing a rapid, inexpensive, and environmentally friendly method is very necessary. Our team has reported a method to determinate antioxidants based on cloud point extraction (CPE) using tergitol TMN-6 and dodecylpolyoxyethylene ether (AEO9) as the

1  
2  
3  
4 55 extraction solvent<sup>14, 15</sup>.

5  
6 56 Recently, the use of iron oxide magnetic nanoparticles (MNPs) has been found  
7  
8 57 extensive applications in a variety of fields<sup>16-20</sup>. Magnetic solid phase extraction  
9  
10 58 (MSPE) based on MNPs is an efficient method for separation and preconcentration of  
11  
12 59 chemical species. Fe<sub>3</sub>O<sub>4</sub> nano-particles (Fe<sub>3</sub>O<sub>4</sub> NPs) played an important role in our  
13  
14 60 work due to their high surface area and excellent chemical selectivity<sup>21-25</sup>. However,  
15  
16 61 bare Fe<sub>3</sub>O<sub>4</sub> NPs can encounter limitations in practical applications, and the  
17  
18 62 hydrophobic surface would mean that the particles cannot disperse well into aqueous  
19  
20 63 solutions<sup>26</sup>. Previous studies have shown that coating the nanomaterials with cationic  
21  
22 64 surfactant cetyltrimethylammonium bromide (CTAB) could greatly inhibit the  
23  
24 65 aggregation of nanoparticles<sup>27</sup>.

25  
26 66 In this paper, Fe<sub>3</sub>O<sub>4</sub> NPs were synthesized via a simple chemical co-precipitation  
27  
28 67 method and the surface was modified by CTAB (designated Fe<sub>3</sub>O<sub>4</sub>@CTAB).  
29  
30 68 Antioxidants were adsorbed onto Fe<sub>3</sub>O<sub>4</sub>@CTAB which positively charged CTAB ions  
31  
32 69 were adsorbed onto the negatively charged Fe<sub>3</sub>O<sub>4</sub> NPs surface. The proposed method  
33  
34 70 was applied to the separation and preconcentration of antioxidants included  
35  
36 71 2,2'-methylenebis (6-tert-butyl-4-methylphenol) (Cyanox 2246), pentaerythritol  
37  
38 72 tetrakis (3-(3,5-di-tert-butyl-4-hydroxyphenyl)propionate) (Irganox 1010),  
39  
40 73 1,3,5-trimethyl -2,4,6-tris(3,5-di-tert-butyl-4-hydroxybenzyl)benzene (Irganox 1330)  
41  
42 74 in plastic packaging injections prior to be determined by HPLC-UV detection.

## 43 75 **2. Materials and method**

### 44 76 **2.1. Instrumentation and chromatographic conditions**

45  
46 77 A scanning electron microscopy (SEM) scanning system VEGA3 SBH (Tescan,  
47  
48 78 Czech Republic) with a tungsten electron gun was used to provide electron beam  
49  
50 79 irradiation was used for characterization of Fe<sub>3</sub>O<sub>4</sub> NPs. Powder XRD patterns of  
51  
52 80 Fe<sub>3</sub>O<sub>4</sub> NPs and Fe<sub>3</sub>O<sub>4</sub>@CTAB were collected on a Rigaku D/max 2200 powder  
53  
54 81 diffraction meter (Rigaku, Japan). Fourier transformed infrared spectroscopy of Fe<sub>3</sub>O<sub>4</sub>  
55  
56 82 NPs and Fe<sub>3</sub>O<sub>4</sub>@CTAB were obtained from IRTracer-100 (SHIMADZU, Japan) in  
57  
58 83 400-4000 cm<sup>-1</sup> wavenumber range. pH-meter Sartorius PB10 (Gttingen, Germany)  
59  
60 84 was used to determine the pH value of solution. Vacuum drying oven BPZ-6033

1  
2  
3  
4 85 (Shanghai, China) was used to dry synthesized nanomaterials. The chromatographic  
5 86 experiments were carried out with Agilent 1100 series high-performance liquid  
6  
7 87 chromatography (HPLC) system (Agilent Technologies, U.S.A.) equipped with a  
8  
9 88 reversed phase C18 analytical column of  $150 \times 4.6$  mm (Agilent TC-C18), maintained  
10  
11 89 at  $25$  °C. The conditions of chromatographic method were as follows: the mobile  
12  
13 90 phase was 100% acetonitrile, the flow rate was  $1 \text{ mL min}^{-1}$ , the injections volume was  
14  
15 91  $20 \mu\text{L}$ , and the detection wavelength was set at  $276 \text{ nm}$ .

## 16 92 **2.2. Materials**

17  
18 93  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ , ammonium nitrate (Tianjin zhiyuan, China),  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  (Shanghai  
19  
20 94 Aladdin, China), cetyltrimethylammonium bromide (Shanghai Bo'ao, China) were  
21  
22 95 all of analytical reagent grade. Acetonitrile of HPLC grade was purchased from  
23  
24 96 Merck (Darmstadt, Germany). Deionized water provided by a Milli-Q system  
25  
26 97 (Millipore, Bedford, MA, U.S.A.). Standards of hindered phenolic antioxidants were  
27  
28 98 supplied by Sigma (St. Louis, Mo., U.S.A.), and the structures were shown in Fig. 1.  
29  
30 99 A stock standard solution containing  $0.4 \text{ mg mL}^{-1}$  of antioxidants were dissolved in  
31  
32 100 acetonitrile and kept in a freezer ( $4^\circ\text{C}$ ).

## 33 101 **2.3. Preparation of modified magnetic iron oxide nanoparticles**

34  
35 102 The  $\text{Fe}_3\text{O}_4$  NPs were synthesized by the co-precipitation method with some  
36  
37 103 modification, briefly  $5.0 \text{ g FeCl}_2 \cdot 4\text{H}_2\text{O}$  and  $6.8 \text{ g FeCl}_3 \cdot 6\text{H}_2\text{O}$  were dissolved in  $50$   
38  
39 104 mL of deionized water, the mixture was added dropwise into  $50 \text{ mL}$  buffer solution of  
40  
41 105 ammonia solution / ammonium nitrate ( $\text{pH}=10$ ) under vigorous stirring and nitrogen  
42  
43 106 gas protection,  $30 \text{ mL}$  ammonia solution were also added dropwise into the reaction  
44  
45 107 solution at the same time. The obtained  $\text{Fe}_3\text{O}_4$  NPs were separated by an external  
46  
47 108 supermagnet after  $30 \text{ min}$ , washed with deionized water for four to five times and  
48  
49 109 vacuum-dried at  $60$  °C for  $12 \text{ h}$ .

50  
51 110 The  $\text{Fe}_3\text{O}_4$  NPs were functionalized with CTAB according to a similar process  
52  
53 111 presented in literature<sup>28</sup>. Briefly  $90 \text{ mg}$  of CTAB was dispersed in  $10 \text{ mL}$  of deionized  
54  
55 112 water, then  $0.1 \text{ g}$  of dried  $\text{Fe}_3\text{O}_4$  NPs was added into the solution and sonicated ( $200 \text{ W}$ ,  
56  
57 113  $40 \text{ kHz}$ ) for  $30 \text{ min}$ . The obtained  $\text{Fe}_3\text{O}_4@$ CTAB NPs were collected with an external  
58  
59 114 supermagnet. After washed with deionized water for three times, the  $\text{Fe}_3\text{O}_4@$ CTAB  
60

1  
2  
3  
4 115 were diluted to 10 mL with deionized water and stored in a freezer (4 °C) for further  
5  
6 116 use, the concentration of Fe<sub>3</sub>O<sub>4</sub>@CTAB suspension was estimated to be about 10 mg  
7  
8 117 mL<sup>-1</sup>.

#### 9 118 **2.4. MSPE Procedure**

10  
11 119 Fe<sub>3</sub>O<sub>4</sub>@CTAB was used in MSPE procedure for separation, preconcentration of  
12  
13 120 antioxidants. First, 200 µL stock standard solution was diluted with deionized water to  
14  
15 121 10 mL in a vial, and 100 µL of Fe<sub>3</sub>O<sub>4</sub>@CTAB suspension was added into this solution.  
16  
17 122 After completely mixing, the magnetic adsorbents were collected by an external  
18  
19 123 supermagnet. The supernatant was decanted and the adsorbed analytes were eluted  
20  
21 124 with 2 mL acetonitrile for twice, and the eluate was injected into the HPLC system for  
22  
23 125 analysis after filtered with 0.45 µm polyether sulfone filters. The blank tests were  
24  
25 126 carried out under the same conditions with blank solution without adding any analytes.  
26  
27 127 For the real sample analysis, 1 mL of injections was diluted with deionized water to a  
28  
29 128 volume of 10 mL before the quantification of antioxidants. The digital pictures  
30  
31 129 showed the phenomena of Fe<sub>3</sub>O<sub>4</sub>@CTAB dispersed in sample solution (a) and  
32  
33 130 collected by supermagnet (b). The procedures of adsorption and magnetic separation  
34  
35 131 could be finished within 2 minutes.

### 36 132 **3. Results and discussion**

#### 37 133 **3.1. Characterization of adsorbents**

38  
39 134 The SEM-images of synthesized Fe<sub>3</sub>O<sub>4</sub> NPs (Fig. 3 i , ii) showed homogeneous  
40  
41 135 distribution of particles and the determined particle size in the case of Fe<sub>3</sub>O<sub>4</sub> NPs were  
42  
43 136 identified in the range of 100-300 nm. Absorption peaks were observed in FT-IR  
44  
45 137 spectra of Fe<sub>3</sub>O<sub>4</sub> NPs (Fig. 3 iii) and Fe<sub>3</sub>O<sub>4</sub>@CTAB (Fig. 3 iv), the band at 550-650  
46  
47 138 cm<sup>-1</sup> could reflect the vibration of Fe-O groups<sup>29</sup>. The peaks at 1450, and 2800, 2900  
48  
49 139 cm<sup>-1</sup> could be assigned to the stretching vibrations of -C-CH<sub>2</sub> and -C-H groups<sup>30</sup>,  
50  
51 140 respectively. These bands are known to be the characteristic bands of CH<sub>2</sub> groups  
52  
53 141 which are presented in CTAB, demonstrated that CTAB had been successfully coated  
54  
55 142 onto the surface of Fe<sub>3</sub>O<sub>4</sub> NPs. The crystalline structures of the nanoparticles were  
56  
57 143 identified with XRD. For Fe<sub>3</sub>O<sub>4</sub> NPs (Fig. 3 v ), diffraction peaks with 2θ of 30.4°,  
58  
59 144 35.6°, 43.3°, 57.3°, and 62.8° were observed, indicating a cubic spinel structure of the  
60

1  
2  
3  
4 145 magnetite <sup>31</sup>. The same sets of characteristic peaks were also observed for  
5  
6 146 Fe<sub>3</sub>O<sub>4</sub>@CTAB (Fig. 3 vi), indicating the stability of the crystalline phase of Fe<sub>3</sub>O<sub>4</sub>  
7  
8 147 NPs during CTAB coating.

### 9 148 **3.2. Optimization of the MSPE conditions**

10  
11 149 In order to select the optimum MSPE conditions for the extraction of antioxidants,  
12  
13 150 10 mL deionized water spiked with 200 μL (0.4mg mL<sup>-1</sup>) antioxidants was used to  
14  
15 151 study the extraction performance of the MSPE, Fe<sub>3</sub>O<sub>4</sub>@CTAB was used as adsorbent  
16  
17 152 which containing 0.9 % (w/v) of CTAB in 10 mL aqueous solution (containing 0.1 g  
18  
19 153 of Fe<sub>3</sub>O<sub>4</sub> NPs). All the experiments were performed in triplicate and the means of the  
20  
21 154 results were used for optimization.

#### 22 155 **3.2.1. Effect of the amount of surfactant**

23  
24 156 The ideal amount of CTAB was determined by coating 0-1.2 % (w/v) of this  
25  
26 157 compound on the surface of Fe<sub>3</sub>O<sub>4</sub> NPs. As can be seen (Fig. 4.), in the absence of  
27  
28 158 surfactant, the analytes were hardly adsorbed to the magnetic adsorbent. The  
29  
30 159 adsorption of antioxidants increases remarkably with increasing the amount of CTAB  
31  
32 160 up to 0.6 %, this can be explained by gradual formation of hemimicelles layer, then  
33  
34 161 the recovery increased slightly until 0.9 % of CTAB was added, which show  
35  
36 162 formation of admicelles. A decrease in the recovery after this amount can be attributed  
37  
38 163 to the formation of micelles in the bulk aqueous solution causing re-distribution of the  
39  
40 164 analytes. Thus, the optimum amount of CTAB was 0.9 % in 10 mL Fe<sub>3</sub>O<sub>4</sub>@CTAB  
41  
42 165 suspension which containing 0.1 g of Fe<sub>3</sub>O<sub>4</sub> NPs.

#### 43 166 **3.2.2. Effect of the amount of adsorbent**

44  
45 167 The amount of adsorbent was an important parameter, the adsorption behavior of  
46  
47 168 the amount of adsorbent was investigated and the result was shown in Fig. 5. The  
48  
49 169 maximum recoveries was obtained at 100 μL of adsorbent, too much or too little was  
50  
51 170 not suitable for the adsorption efficiency, the analytes could not be completely  
52  
53 171 adsorbed at 50 μL of adsorbent, and the analytes were not easily eluted from the  
54  
55 172 adsorbent when the dosage of adsorbent was too large. According to the results, 100  
56  
57 173 μL of Fe<sub>3</sub>O<sub>4</sub>@CTAB suspension was selected in the following experiments.

#### 58 174 **3.2.3. Effect of solution pH**

1  
2  
3  
4 175 The pH of the solution was one of the prime factors affecting the adsorption  
5 176 behavior of mixed hemimicelles system. The surface of Fe<sub>3</sub>O<sub>4</sub>@CTAB were  
6  
7 177 positively charged when the pH value was below the point of zero charge (PZC)  
8  
9 178 which was reported to be 6.4 previously<sup>31</sup>. In this study, the effect of solution pH was  
10  
11 179 investigated by varying the parameter in the range of 3–13. As shown in Fig. 6, the  
12  
13 180 magnetic adsorbents exhibited low adsorption of antioxidants when the pH value was  
14  
15 181 below 5 that because Fe dissolved from Fe<sub>3</sub>O<sub>4</sub>@CTAB dispersed in the acidic  
16  
17 182 solution, and the solution became dark brown and only partial antioxidants were  
18  
19 183 collected. With the pH value ranged from 9 to 13, the Fe<sub>3</sub>O<sub>4</sub>@CTAB surface became  
20  
21 184 negatively charged, the bonding interaction between Fe<sub>3</sub>O<sub>4</sub>@CTAB and antioxidants  
22  
23 185 (which are also negatively charged at this pH range) would be decreased. The pH of  
24  
25 186 sodium chloride injections and glucose injection were determined to be about 5.36  
26  
27 187 and 4.48, respectively. The pH ranged from 5.43 to 5.66 after the concentration of the  
28  
29 188 samples solution diluted in 10 times, which showed good recoveries. Therefore, there  
30  
31 189 was no need to adjust the pH of test solution.

#### 32 190 **3.2.4. Effect of salt content of the sample**

33  
34 191 The extraction efficiency can also be enhanced by the addition of salt. Its effect on  
35  
36 192 the extraction efficiency was investigated by varying the concentration of NaCl in the  
37  
38 193 standard solution. The results (shown as Fig. 7) showed that the recoveries remained  
39  
40 194 above 85% with the concentration of NaCl ranged from 0.00 to 0.02 mol L<sup>-1</sup> in the  
41  
42 195 test solution, and the optimum recoveries were obtained without the addition of NaCl.  
43  
44 196 The same inhibition trends were also observed by Gao et al.<sup>32</sup> which used graphene  
45  
46 197 oxide as adsorbent, as previously reported, the added NaCl can influence adsorption  
47  
48 198 capacities of tetracycline on graphene oxide by the electrostatics screening effect. We  
49  
50 199 supposed that the adsorption of antioxidants on Fe<sub>3</sub>O<sub>4</sub>@CTAB would be influenced  
51  
52 200 by cation- $\pi$  interaction between analytes and Na<sup>+</sup>. The electron-rich  $\pi$  system above  
53  
54 201 and below the benzene ring hosts a partial negative charge, the negatively charged  
55  
56 202 region can then interact favorably with positively charged species such as Na<sup>+</sup>, so the  
57  
58 203 electrostatic interaction between Fe<sub>3</sub>O<sub>4</sub>@CTAB and antioxidants would be decreased.  
59  
60 204 As is known to all, the concentration of NaCl in sodium chloride injections is about

1  
2  
3 205 0.15 mol L<sup>-1</sup>, there was no need to add NaCl in sample solution.  
4

### 5 206 **3.2.5. Effect of sorption time**

6  
7 207 The effect of sorption time was carried out at the optimal condition, the separation  
8  
9 208 and preconcentration of antioxidants was fast and effective, the adsorption was almost  
10  
11 209 completed within 2 min.

### 12 210 **3.2.6. Effect of solution volume**

13  
14 211 Mixed hemimicelles SPE procedure based on magnetic carrier technology avoids  
15  
16 212 many time-consuming steps such as column passing sample loading and filtration and  
17  
18 213 shows a great potential for preconcentration of large volume samples. The volume of  
19  
20 214 test solution was investigated by varying the parameter in the range of 10, 50 and 100  
21  
22 215 mL, while the dosages of standards were kept in 80 µg. The result was shown as Fig.  
23  
24 216 8. With the volume of test solution increased, the recoveries showed a declined  
25  
26 217 tendency. Thus, 10 mL was selected as optimum value for the next experiments.

### 27 218 **3.2.7. Desorption conditions**

28  
29 219 Desorption of the analytes from the magnetic adsorbent was studied by using  
30  
31 220 different organic solvents (methanol, acetonitrile, acetone), and the effect of  
32  
33 221 desorption solution volume on desorption efficiency of the analytes was also  
34  
35 222 investigated. As a result (Fig. 9), the recoveries for three desorption solvents were  
36  
37 223 higher than 85%, the eluting power of acetonitrile and methanol were equivalent and  
38  
39 224 stronger than acetone. However, the adsorbent dispersed in methanol was difficult to  
40  
41 225 collect, which would take almost 5 min, and the chromatogram eluted with acetone  
42  
43 226 showed a strong UV absorption peak at 276 nm (the cut-off wavelength of acetone is  
44  
45 227 330nm) which had an effect on the target analytes. It was also found that all analytes  
46  
47 228 could be quantitatively desorbed from the sorbent by rinsing the sorbent with 2 mL  
48  
49 229 acetonitrile for twice. Thus, 2 mL acetonitrile was selected as the optimum desorption  
50  
51 230 condition.

### 52 231 **3.3. Analytical performance**

53  
54 232 The calibration curves were obtained from peak areas of the reference standards  
55  
56 233 against their concentrations, a series of the standard mixture solutions concentration  
57  
58 234 ranges were selected (regression coefficients ( $R^2$ )  $\geq 0.999$  for all analytes) to get a  
59  
60

1  
2  
3 235 good linearity. The LOD of proposed method was in the range from 0.14 to 0.15  $\mu\text{g mL}^{-1}$   
4  
5 236 based on the ratio of signal-to-noise ( $S/N = 3$ ), and the LOQ of proposed method was in  
6  
7 237 the range from 0.45 to 0.50  $\mu\text{g mL}^{-1}$  based on the ratio of signal-to-noise ( $S/N = 10$ ).  
8  
9 238 Detail information regarding the calibration curves, linear ranges, and relative  
10  
11 239 standard deviations (RSD) was shown in Table 1. The typical HPLC chromatograms  
12  
13 240 of separated and preconcentrated antioxidants were shown as Fig. 10.

### 241 **3.4. Analysis of injections**

242 The validity of the proposed method was examined for the adsorption and  
243 desorption of antioxidants migrated from polypropylene bottles to injections.  
244 Injections include sodium chloride injections (100mL and 500mL), glucose injection  
245 (100mL) were purchased from the university hospital (Kunming, China). The  
246 recoveries and repeatability for antioxidants in injections were tested by adding  
247 different amounts of standards, the detail data were listed in Table 2. As can be seen,  
248 The mean recoveries were in the range from 85.0 to 93.5% at 5, 10, and 20  $\mu\text{g mL}^{-1}$   
249 spiked levels, and the RSDs were in the range from 1.16 to 2.81%.

### 250 **3. 5. Reusability of adsorbent**

251 In order to investigate the recycling of the adsorbent under optimized conditions,  
252 the adsorbent were rinsed sequentially with methanol and acetonitrile alternately, and  
253 deionized water ( $2 \times 5$  mL) before application in the next time. No obvious changes  
254 were observed in the recoveries for 3 times (Table.3). The results of this study  
255 indicate that the adsorbent is reusable without a considerable loss in its adsorption  
256 efficiency during extraction procedure.

### 257 **4. Conclusions**

258 In this study, a fast, simple, stable method for separation and preconcentration of  
259 migration levels of Cyanox 2246, Irganox 1010, Irganox 1330 in injections has been  
260 developed. This method involved MSPE of antioxidants with  $\text{Fe}_3\text{O}_4@\text{CTAB}$  and the  
261 determination by HPLC, the as-prepared  $\text{Fe}_3\text{O}_4@\text{CTAB}$  had an average diameter  
262 about 200 nm. It was notable that the separation and preconcentration of those  
263 antioxidants were fast and could be finished within two minutes. Moreover, the  
264 consumption of organic solvent was greatly reduced compared with classical methods

1  
2  
3 265 such as LLE, SPE and so on. The achieved results in the studies showed the potential  
4  
5 266 applications of this method, it is recommended to support drugs security  
6  
7 267 determination of antioxidants in injections.
