Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

20 **Abstract**

21 For rapid evaluation of fish freshness, a colorimetric sensor array has been developed  
22 for the sensitive detection to measure simultaneously TVB-N and K value of fish  
23 during its storage period. Silver carps were taken as fish samples which were stored at  
24 constant temperature of 4°C during experiment period. 10 kinds of porphrin  
25 compounds and 6 pH indicators were selected as chromogenic materials in this  
26 experiment according to the previous study and the theoretical research. For  
27 comparison, total volatile basic nitrogen (TVB-N) values of fishes were tested by  
28 conventional chemical method, and the K-values were measured using High  
29 Performance Liquid Chromatography (HPLC). As sensing materials used in the sensor  
30 array were chromogenic, the color of the sensor array changed when reacting with  
31 odor emitted by fish sample. The color change profiles of the sensor array before and  
32 after exposure to the odor of each sample were got using image processing method.  
33 And color features were extracted to be analyzed using principal component analysis  
34 (PCA), linear discriminant analysis (LDA). The relationship between these analysis  
35 results and the TVB-N values and K-values obtained by conventional methods were  
36 established using support vector regression (SVR). And therefore models were set up  
37 for rapid prediction of TVB-N values and K-values, respectively. For the SVR model  
38 of TVB-N content and K-values, calibration correlation coefficient ( $R_{tr}$ ) was 0.8564  
39 and 0.8712, and the root mean square error of calibration (RMSEC) was 4.2177 and  
40 0.06127, respectively. It is feasible to predict TVB-N values and K-values according  
41 to experiment results of colorimetric sensor array. The results indicated that the novel  
42 method based on colorimetric sensor array developed provide a feasible way for rapid  
43 and nondestructive evaluation of fish freshness.

5 36 **1.0 Introduction**

6  
7 37 For thousands of years, the fish product is deeply favored by the people in many  
8  
9 38 countries as it is rich in protein and of delicious taste. However, fish also has the  
10  
11 39 disadvantage of comparatively short shelf life (Yao, Zhang et al. 2011). Public  
12  
13 40 attention to fish quality and safety has increased significantly in recent decades, due in  
14  
15 41 part to changes in consumer behavior and the gradually increasing consumption of  
16  
17 42 fish. The safety of fish is of course important to consumer. Loss of freshness and  
18  
19 43 spoilage of fish are rather complex processes and various factors such as microbiology,  
20  
21 44 enzyme influence the spoilage pattern. In fact, the development of reliable methods to  
22  
23 45 assess fish freshness and to evaluate quality criteria has been researched for many  
24  
25 46 years (Di Natale, Olafsdottir et al. 2001). The traditional methods for determining fish  
26  
27 47 freshness are based on physical, chemical, microbiological measurement and human  
28  
29 48 sensory evaluation (Olafsdottir, Nesvadba et al. 2004). The human array evaluation is  
30  
31 49 an immediate assessment of quality and can be done with no damage to fish. On the  
32  
33 50 other hand, it is not easy to keep evaluation results consistent among different  
34  
35 51 assessments, because the evaluation score is subjective. Other methods including  
36  
37 52 microbiological measurement and chemical methods are limited in the laboratory and  
38  
39 53 not convenient on-site because they are time consuming and destructive detection.  
40  
41 54 Instrumental method independent of the subjective opinion of human judge is needed  
42  
43 55 to meet the demand for quality measurement in the fish industry.

44  
45 56 Recently, plentiful rapid instrumental analytical techniques also have been  
46  
47 57 developed for the sensitive detection of the spoilage of fish, such as near infrared  
48  
49 58 (NIR) spectroscopy (Armenta, Coelho et al. 2006), electronic tongue (Han, Huang et  
50  
51 59 al. 2014), and electronic nose (Limbo, Sinelli et al. 2009). Odor is one of the most  
52  
53 60 important parameters for evaluating the freshness of food. Once the fish dies, a very  
54  
55 61 large amount of microbes of fish breed produces volatile organs (VOCs), which are  
56  
57 62 closely related to the freshness of fish. Each product has a characteristic profile of  
58  
59 63 volatile compounds and therefore its own characteristic odor. Likewise, spoilage will  
60  
61 64 result in a different but still characteristic profile of volatile compounds in the same  
62  
63 65 product. Kenneth has previously reported the colorimetric array detection of a wide  
64  
65 66 range of odorants, using a family of metalloporphyrins immobilized on reverse-phase  
66  
67 67 silica and on hydrophobic membranes (Suslick, Rakow et al. 2004). Gas sensor array,  
68  
69 68 a new concept of electronic nose, compared with traditional electronic nose, the  
70

1  
2  
3 69 technology has the advantages of high precision, wide range and it is not influenced  
4 70 by humidity (Huang, Xin et al. 2009). It transformed olfactory information into visual  
5 71 information by color's change after pigments reacted with volatile compounds and  
6 72 chemometrics analysis was carried out on the visual information (Zou and Zhao 2008).  
7  
8 73 In the past decades, many kinds of colorimetric sensors have been developed to  
9 74 monitoring food freshness based on different chromogenic materials. Artificial  
10 75 olfaction system has been applied to the analysis of beer (Zhang, Bailey et al.  
11 76 2006) and soft drink (Zhang and Suslick 2007, Chen, Liu et al. 2013), classification of  
12 77 tea (Chen, Liu et al. 2013), evaluation of pork freshness, and monitor fish packaging  
13 78 (Kuswandi, Restyana et al. 2012). Our previous research also has applied colorimetric  
14 79 sensor array to evaluate fish freshness (Huang, Xin et al. 2011). Researches  
15 80 mentioned above show that an artificial olfactory technique based on colorimetric  
16 81 sensor array has huge potential in the analysis of food, according to their volatile  
17 82 organic compounds (VOCs).

18 83 Silver carps were taken as fish samples in this study. Because the silver carp is  
19 84 different from other fish detected before in physical size and composition, it is  
20 85 necessary to optimize the test parameters including the way of gas sampling and array  
21 86 keeping. In previous study, volatile organic compounds were acquired by applying  
22 87 carrier gas to bring the top gas of sample to reaction chamber and the colorimetric  
23 88 sensor array was kept in a nitrogen atmosphere. In this study, volatile organic  
24 89 compounds were acquired by free-diffusion in reaction chamber and each array was  
25 90 kept in a Hermetic bag.

26 91 This study is therefore intended to develop an E-nose system of fish freshness  
27 92 based on TVB-N and K-values, regarding the silver carp which has the largest  
28 93 products and sales as detection object. The detailed work was arranged as follows: (1)  
29 94 fabricating an E-nose system of colorimetric sensor arrays (2) determining chemical  
30 95 indicators (3) using Fisher linear discriminant (Fisher LDA) for sensors data  
31 96 classification, and support vector regression (SVR) models for prediction of quality  
32 97 parameters (TVB-N and K-values).

## 33 98 **2.0 Materials and methods**

### 34 99 2.1. Samples preparation

35 100 Silver carp fishes (*Hypophthalmichthys molitrix*) from a local aquaculture farm  
36 101 of average size of 950g were adopted in the experiment. Before the tests, all the fishes  
37 102 were cleaned, weighted and were individually placed in freshness protection packages.

1  
2  
3 103 The samples were then stored in a refrigerator at 4°C. The chemical and E-nose  
4 104 analyses of the samples were conducted every day and lasted for 12 days.

## 5 105 2.2. Colorimetric sensor array

6  
7  
8 106 Fabricating a colorimetric sensor array is often based on two crucial requirements:

9  
10 107 (1) every chemically responsive dye must contain a center interacted strongly with  
11 108 analytes, and (2) the interaction center must be strongly coupled to an intense  
12 109 chromophore. The required dye classes include: (i) Lewis acid/base dyes (i.e., metal  
13 110 ion containing dyes), (ii) Brønsted acidic or basic dyes (i.e., pH indicators), and (iii)  
14 111 dyes with large permanent dipoles (i.e., zwitterionic solvatochromic dyes) (Janzen,  
15 112 Ponder et al. 2006) Porphyrins and their metal complexes are a natural choice for  
16 113 recognition of analytes with Lewis acid/base capabilities. Metalloporphyrins are  
17 114 nearly ideal for the detection of metal-ligating vapors because of their open  
18 115 coordination sites for axial ligation, their large spectral shifts upon ligand binding, and  
19 116 their intense coloration. Common pH indicator dyes change color in response to  
20 117 changes in the proton (Brønsted) acidity or basicity of their environment (Suslick,  
21 118 Rakow et al. 2004). Colorimetric sensor array was made by printing the chemical  
22 119 responsive dyes on the hydrophobic plate, silicagel plate which were used as the plate  
23 120 of the sensor array in the experiment according to the experiment conducted before  
24 121 (Huang, Xin et al. 2011). To choose optimum chromogenic sensing materials, the  
25 122 characteristic gases of silver carps were determined by Gas Chromatography-Mass  
26 123 Spectrometer (GC-MS). Combined with the theoretical research (Gu, Huang et al.  
27 124 2014, Gu, Huang et al. 2014, Huang, Gu et al. 2014), ten porphyrin compounds and  
28 125 six pH indicators were used as sensing pigments. The colorimetric sensor array was  
29 126 prepared by placing each material onto the silicagel plate to obtain a 4×4 array. The  
30 127 ten porphyrins or metalloporphyrins materials were purchased from Sigma Chemical  
31 128 (USA), including:

32  
33  
34  
35  
36  
37 129 5, 10, 15, 20-Tetraphenyl-21H, 23H-porphine manganese (III) chloride

38 130 Zinc 2, 3, 9, 10, 16, 17, 23, 4-octakis-(octyloxy)-29H, 31H-phthalocyanine

39 131 2, 3, 7, 8, 12, 13, 17, 18-Octaethyl-21H, 23H-porphine manganese (III) chloride

40 132 5, 10, 15, 20-Tetraphenyl-21H, 23H-porphine copper (II)

41 133 5, 10, 15, 20-Tetraphenyl-21H, 23H-porphine zinc, (low chlorin, synthetic)

42 134 5, 10, 15, 20-Tetrakis (pentafluorophenyl)-21H, 23H-porphyrin iron (III) chloride

43 135 5, 10, 15, 20-Tetraphenyl-21H, 23H-porphine

7 138 5, 10, 15, 20-Tetraphenyl-21H, 23H-porphine nickel (II)  
8  
9 139 Six types of pH indicators were obtained from Sinopharm Chemical Reagent Co. Ltd.,  
10  
11 140 including: (1) Bromocresol Green, (2) Bromothymol Blue, (3) Methyl Red, (4)  
12  
13 141 Neutral Red, (5) Bromocresol Purple, and (6) Cresol Red.

14  
15 142 The detailed steps of fabricating colorimetric sensor were arranged as follow: (1)  
16  
17 143 dissolve the porphyrins and metalloporphyrin materials in chloroform, and dissolve  
18  
19 144 the pH indicators in ethanol and; (2) 16 kinds of pigments solution of 2 mg/mL were  
20  
21 145 eventually obtained after ultrasound for hours;(3) Each pigments solution was printed  
22  
23 146 on the plate using 0.1  $\mu$  L microcapillary pipettes, constructing a 4 $\times$ 4 sensor array; (4)  
24  
25 147 dried the sensor arrays in fume hood, and kept each of them in a Hermetic bag before  
26  
27 148 use.

### 28 149 2.3. E-nose system and data acquisition

29  
30 150 A fully functional prototype device for fish was constructed and the schematic  
31  
32 151 diagram is shown in Fig 1. The enriched VOCs from samples were collected by free  
33  
34 152 diffusion. In this experiment, the details were as follows: (1) an initial image was  
35  
36 153 acquired before a sensor was used by HP scanjet 4890 flatbed scanner. (2) A complete  
37  
38 154 fish was put in the sample room, and then the prepared sensor array chips were  
39  
40 155 stucked on the sealing cap, with the surface containing pigments facing down. And (3)  
41  
42 156 a final image was acquired after chubs' headspace volatile gas reacted with the  
43  
44 157 chromogenic materials on the sensor array for 2 minutes.

45  
46 158 The response of each of the sixteen pigments in the sensor was represented by  
47  
48 159 the red, green and blue values, which resulted in a 48 dimensional vector (16dyes $\times$ 3  
49  
50 160 color components RGB). This visual representation extracted from differences of  
51  
52 161 images before and after experiment was obtained in the environment of OPENCV. All  
53  
54 162 the data of RGB components were used in statistical and quantitative analyses and  
55  
56 163 subsequent pattern recognition.

### 57 164 2.4. TVB-N and K-values

58  
59 165 The total volatile basic nitrogen is one of the main physical and chemical  
60  
166 experiments to evaluate the freshness of fish. The total volatile basic nitrogen of each  
167  
168 fish samples was measured with micro Kjeldahl method according to SC/T3032-2007  
(South China Sea fisheries research institute 2007). A 10g portion of sample was

1  
2  
3 169 taken aseptically and homogenized after adding 90mL perchloric acid solution. It was  
4 170 filtered and the filtrate was directly distilled, and then titrated.

5  
6 171 The ATP-related compounds, consisting of inosine-50-monophosphate (IMP),  
7 172 inosine (Ino), and hypoxanthine (Hx), were extracted by perchloric acid and separated  
8  
9 173 and quantified by high-performance liquid chromatography. The analysis was  
10 174 conducted on a high-performance liquid chromatography (Ultimate 3000 Germany  
11 175 DIONEX Company). Separations were made on a reverse-phase Ultrabase  
12 176 C184.6×150 mm, with an internal particle diameter of 5μm (Shimadzu inertsustain).  
13 177 ATP, ADP, AMP, IMP, HxR and Hx were quantified according to the external standard  
14 178 method using calibration curves of the peak area of compound versus the compound  
15 179 concentration under identical chromatographic conditions. K-values were then  
16 180 calculated according to Eq (1).

17  
18  
19  
20  
21  
22  
23  
24 181 
$$K(\%) = \frac{100(HxR + Hx)}{ATP + ADP + AMP + IMP + HxR + Hx} \quad (1)$$

25  
26 182 Where ATP, ADP, AMP, IMP, HxR, Hx represent the concentration (μmol/g) of  
27 183 adenosine triphosphate, adenosine diphosphate, adenosine monophosphate, inosine  
28 184 monophosphate, inosine, hypoxanthine.

## 29 185 2.5. Statistical method

30  
31  
32 186 In the data processing, Fisher linear discriminant (Fisher LDA) and support  
33 187 vector regression (SVR) were used for statistical analysis. All the analyses were  
34 188 performed using Matlab 2012a (Mathworks, Natick, MA) in windows 7.

## 35 189 **3.0 Results and discussions**

### 36 190 3.1. Physico-chemical analyses

#### 37 191 3.1.1 Measurement of TVB-N by conventional methods

38  
39 192 The initial TVB-N content of the fish (Fig. 2(a)) was 12.6mg/100g (at Day 1)  
40 193 and the final TVB-N was up to 45.7mg/100g, which could be related to the activity of  
41 194 spoilage bacteria and endogenous activities. TVB-N of silver carp fish remained  
42 195 stable up to day 4, and slightly increased during day 4~day 7 and strongly increased  
43 196 thereafter. In the present study, an arbitrary value for TVB-N of 13mg/100g was taken  
44 197 for the upper acceptability limit of fresh fish and 20mg/100g was used to mark the  
45 198 value of not edible (South China Sea fisheries research institute 2007). The two values  
46 199 were exceeded on day 2 and day 8.

#### 47 200 3.1.2 ATP related compounds and K-values measured by HPLC

48 201 The ATP in the fish muscle would degrade in the way of ATP → ADP → AMP

1  
2  
3 202 → IMP → HxR → Hx after fish was died. From Fig. 2(b), the changes of inosine  
4  
5 203 5'-monophosphate (IMP) and hypoxanthine (HX) were depicted during a cold storage  
6  
7 204 of 12 days. The IMP levels at the beginning of the study were at the average of 5  $\mu$   
8  
9 205 mol/g. The concentration of this metabolite progressively decreased throughout  
10  
11 206 storage with levels under 1.24  $\mu$  mol/g at the end of this study. HX values increased  
12  
13 207 slowly and remained at low levels during the 12 days of this study.

14 208 The K-values (Fig. 2(c)), which measures the extension of IMP degradation, was  
15  
16 209 worked out to reduce this variability. The K-values increased during storage from  
17  
18 210 values 10%~52%. The K-values rises faster in the first three days because when it  
19  
20 211 becomes stiff, ATP decomposes quickly, K-values increase rapidly and during this  
21  
22 212 time, protein decomposes slowly. Compared with TVB-N, K-values accurately reflect  
23  
24 213 the changes of freshness of the fish in the early time. It is generally believed that the  
25  
26 214 K-values of fresh fish must be 10% (Yang, Xue et al. 2007, Yao, Zhang et al. 2011),  
27  
28 215 the K-values of fresh goods such as sashimi in Japan 20%, the K-values of the second  
29  
30 216 freshness is 20%~40% and the K-values of the fish which decompose at the first  
31  
32 217 time is 60%~80%. From Fig. 2(c), it can be seen that in the first day of silver carp's  
33  
34 218 storage, its freshness was close to 10%, 18 samples had K-values that are about 10%,  
35  
36 219 and the average value was 10.64%; In the second day, the average of the K-values was  
37  
38 220 up to 19.67% and most of the silver carps fish were still fresh; in the third to the  
39  
40 221 seventh day, the K-values of the samples were in the range of 20%~40% and the  
41  
42 222 silver carps was considered as second level freshness; in the twelfth day, the decay  
43  
44 223 was very obvious.

### 41 224 3.2. The change of visual sensor array response

42 225 Difference maps were obtained by the difference between the red, green and blue  
43  
44 226 (RGB) of each sensing material before and after experiment. The difference in the  
45  
46 227 vector is shown in Fig. 3 as a map of the absolute values of color changes. Fig. 3  
47  
48 228 clearly shows the presence of characteristic color fingerprints for each day, thus  
49  
50 229 confirming the possibility of using this array to monitor fish spoilage. With the  
51  
52 230 changes of the species and the composition of the volatile gases during silver carps'  
53  
54 231 spoilage, almost all the dyes' color changed and the changes was enhanced strength.  
55  
56 232 During the early time of cold storage, the silver carps were fresh and there was less  
57  
58 233 volatile component, most of which were hydrocarbons and short C chain alcohols  
59  
60 234 (Dai, Huang et al. 2012). They could only generate non-specific adsorption with the

1  
2  
3 235 porphyrin-based compound and the sensor response was slight. The response of the  
4 236 pH indicators was more evident than porphyrin-based compound, which were mainly  
5 237 due to the action of a small amount of acid gases. During the medium-term of storage,  
6 238 silver carps were in the second level freshness and the fish began to decompose,  
7 239 producing volatile gases containing of nitrogen, sulfur and so on. As the time of cold  
8 240 storage prolonging, the concentration of some species of the volatile gases in fish  
9 241 began to decrease, while the concentration of the nitrogen-containing and  
10 242 sulfur-containing gases continued to rise. This phenomenon led to the porphyrins  
11 243 response which became more obvious than the pH indicators and the overall color of  
12 244 array was obviously different from that in early times.

### 245 3.3. Correlation between colorimetric sensor array method and conventional method

246 PCA was used for classification of the samples from three types of fish in this  
247 work. PCA is a linear, unsupervised and pattern recognition technique used for  
248 analyzing, classifying and reducing the dimensionality of numerical datasets in a  
249 multivariate problem (Zhao and Lin 2012). It can transform original variables into a  
250 few new variables, known as principal compounds (PCs). To visualize the cluster  
251 trends of these samples, a 3-dimensional scatter plot (see Fig. 4(a)) was constructed  
252 using PC1, PC2 and PC3. Herein, the top three PCs accounted for 82.53% of total  
253 variances in raw data. The first six factors explained 91.2% of total variance. But PCA  
254 is an unsupervised technique and hence LDA was employed. LDA is probably the  
255 most frequently used supervised pattern recognition. The optimal transformation in  
256 classical LDA is obtained by minimizing the within-class distance and maximizing the  
257 between-class distance simultaneously, thus achieving maximum class discrimination  
258 (Zhao and Lin 2012). Similar to PCA, a 2-dimensional plot was constructed using  
259 DF1 and DF2 in this work, and all samples cluster can be visualized in this plot as  
260 shown in Fig. 4(b). DF1 and DF2 can explain almost 100% of total variances.

261 According to TVB-N determination results, the output of the LDA model can be  
262 defined as three levels--- fresh (group-1), not fresh (group-2), not edible (group-3). A  
263 total of 216 samples were ranked in order of spoilage time. All samples were divided  
264 into two sets, one sample taken out from every six samples was assigned to the test set  
265 and the other five samples were assigned to the train set. As a result the train set has  
266 180 samples and the test set has 36 samples. In test set, 6 samples were classified in  
267 error and in train set, 28 samples were classified in error. The accuracy of test set and  
268 train set were 83.33% and 84.44%.

269 Since the PCA and LDA analyses of the colorimetric measurements and  
270 physico-chemical values classified the samples into similar groups, the SVR statistical  
271 tool was used to predict physicochemical values from the optoelectronic array data.  
272 SVR is a novel learning method that has solid theoretical basis and requires only  
273 small amount of sample. Different from present statistical approaches, it doesn't  
274 involve probability measure, law of large numbers and so on. In essence, it avoids  
275 traditional process from induction to deduction, realizing the efficient transductive  
276 inference from training sample to forecast sample, which greatly simplified the  
277 regression process. A rapid increase in TVB-N content with time was accompanied by  
278 parallel in the formation of K-values and the color changes of the colorimetric sensor  
279 array. The input values were the first six factors from PCA. To develop a TVB-N and  
280 K value prediction model, the samples were divided into two sets as before. The  
281 experimental values versus the values predicted by the SVR statistical models for both  
282 TVB-N content and K-values are shown in Fig. 5. Fig. 5 (a) shows the SVR-predicted  
283 TVB-N versus the actual TVB-N, and Fig. 5 (b) shows the SVR-predicted K-values  
284 versus the actual K-values. A preliminary evaluation of the accuracy of the created  
285 prediction model can be made by visually inspecting the difference between the  
286 measured and predicted values. However, a more rigorous analysis was achieved by  
287 linearly or nonlinearly fitting the experimental points. The correlation coefficients  
288 relate to accuracy in the prediction, whereas the root mean square error (RMSEC)  
289 relates to the SVR model's precision (Zhao and Lin 2012). Good correlations between  
290 the gas sensor array results and both TVB-N analysis and K value analysis were  
291 obtained. In the model, for TVB-N, correlation coefficients ( $r^2$ ) of 0.733 and 0.627 in  
292 train set and test set are obtained, while for K value, correlation coefficients ( $r^2$ ) of  
293 0.759 and 0.596 in train set and test set are obtained, respectively. Moreover, values of  
294 4.2177, 4.9563 and 0.06127, 0.0789 were found for RMSEC for the train set and  
295 RMSEP for the test set of TVB-N content and K-values, respectively. In this way, the  
296 ability of the electronic nose to predict TVB-N and K value was investigated for the  
297 fish samples. Due to the good correlation between the colorimetric sensor array and  
298 TVB-N and K value, the colorimetric sensor array could be used as a rapid  
299 non-destructive testing for TVB-N and K Value of Silver Carps and also could be used  
300 for grouping fish freshness.

#### 301 **4.0 Conclusions**

302 A colorimetric sensor array for monitoring fish spoilage has been developed. The

1  
2  
3 303 array consisted of sixteen chromogenic sensing materials including ten porphrin  
4 304 compounds and six pH indicators. The detection of TVB-N content and K-value was  
5 305 also carried out. All fish were classified into fresh, not fresh, not edible according to  
6 306 the test. PCA and Fisher LDA analysis were employed to analyze the chromogenic  
7 307 data from sensor arrays. The images obtained from PCA and Fisher LDA analysis  
8 308 both clearly showed three main clusters that correlated quite well with the  
9 309 classification from chemical analysis. A good correlation was obtained by SVR  
10 310 statistical analysis between the gas sensor array response and both TVB-N content  
11 311 and K value. Compared with the commercial studies, the colorimetric sensor array is  
12 312 just a chip, with no space occupation and simple to make with 3 minutes only. Besides,  
13 313 it is cheap and easy to detect products with no destruction quickly. And considering  
14 314 the relation between the chromogenic data and fish decay, the results indicated that  
15 315 the novel method based on colorimetric sensor array developed provide a feasible way  
16 316 for rapid and nondestructive evaluation of fish freshness.
