**Abstract:** Reaction of Me<sub>3</sub>Al (two equivalents) with *ortho*-, *meta*- or *para*-anisidine, (OMe)(NH<sub>2</sub>)C<sub>6</sub>H<sub>4</sub>, affords the complexes {[1,2-(OMe),N-C<sub>6</sub>H<sub>4</sub>( $\mu$ -Me<sub>2</sub>Al)]( $\mu$ -Me<sub>2</sub>Al)}<sub>2</sub> (**1**), [1,3-(Me<sub>3</sub>AlOMe),NHC<sub>6</sub>H<sub>4</sub>( $\mu$ -Me<sub>2</sub>Al)]<sub>2</sub> (**2**) or [1,4-(Me<sub>3</sub>AlOMe),NHC<sub>6</sub>H<sub>4</sub>( $\mu$ -Me<sub>2</sub>Al)]<sub>2</sub> (**3**), respectively. The molecular structures of **1** - **3** have been determined and all three complexes were found to be highly active for the ring opening polymerization (ROP) of  $\epsilon$ -caprolactone. **1** was found highly active either with or without benzyl alcohol present; at various temperatures, the activity order **1** > **2**  $\approx$  **3** was observed. For the ROP of *rac*-lactide results for **1** - **3** were poor.

## Introduction

The ring opening polymerization (ROP) of cyclic esters to produce biodegradable polymers continues to be an area of immense academic interest. A variety of metal-based initiators have been employed, which operate via a coordination-insertion mechanism. Aluminium complexes too have attracted attention in this area, primarily due to their beneficial toxicity (low) and Lewis acidity (high). [1] Of the previously reported organoaluminium systems, most studies have centred around the use of *N,O*-phenoxyimine (salicylaldimine) type ligand sets (see **I**, chart 1). [2, 3] For example, Nomura and co-workers studied the series of dimethylaluminium complexes [Me<sub>2</sub>Al[O-2-R<sup>1</sup>-6-(R<sup>2</sup>N=CH)C<sub>6</sub>H<sub>3</sub>]] (R<sup>1</sup> = Me, *t*Bu; R<sup>2</sup> = *t*Bu, cyclohexyl, adamantyl, Ph, 2,6-Me<sub>2</sub>C<sub>6</sub>H<sub>3</sub>, 2,6-*i*Pr<sub>2</sub>C<sub>6</sub>H<sub>3</sub>), for which it was found that the imine bound substituent (R<sup>2</sup>) had a significant influence on the observed catalytic activity. [2a,d] As well as other systems derived from other bi-dentate chelates, for example the *N,N*-*O,O*-chelate systems **II** - **IV**, [4] recent studies have also focussed on the use of tri- (eg. **V** and **VI**), [1c, 5] and tetra-dentate ligand sets (eg. **VII** and **VIII**) [6]; macrocyclic ligands have also been studied. [7] These multi-dentate ligands, which are usually derived from amines/anilines, have been shown to yield complexes capable of the ROP of  $\epsilon$ -caprolactone in a living manner, allowing for control over the molecular weight and distribution of the resulting polymer product. [4] We have also found that remote dialkylaluminium centres present in the same complex can have beneficial cooperative effects on the catalytic activity as long as they are not linked by aluminoxane type bonding. [7] With this in mind, we are exploring the potential of functionalised anilines as ancillary ligands at aluminium in the ROP of  $\epsilon$ -caprolactone or *rac*-lactide, where there is the potential for binding multiple organoaluminium centres in relatively close proximity. Herein, we present our findings on systems derived from the interaction of *o*-, *m*-, *p*-anisidines with trimethylaluminium and explore the effect of the structures of the resulting organoaluminium derived species on catalytic

activity in the ROP of  $\epsilon$ -caprolactone; activities for the ROP of *rac*-lactide were very and so further studies were discontinued.

**Chart 1.** Reported organoaluminium ROP pre-catalysts

An attractive feature of the complexes described herein is that they are derived from relatively inexpensive, commercially available precursors, [8] which, unlike most other organoaluminium-based ROP systems, circumvents the need for 'ligand' synthesis prior to complexation.

## Results and Discussion

Interaction of *o*-anisidine with two equivalents of Me<sub>3</sub>Al in toluene afforded the complex {[1,2-(OMe),N-C<sub>6</sub>H<sub>4</sub>(μ-Me<sub>2</sub>Al)](μ-Me<sub>2</sub>Al)}<sub>2</sub> (**1**) in good isolated yield (~ 77 %). Slow cooling of the reaction to 0 °C led to the formation of colourless crystals suitable for a single crystal X-ray diffraction study. The molecular structure of **1** is shown in Figure 1, with selected bond lengths and angles given in the caption. The centrosymmetric dimer possesses slightly asymmetric Me<sub>2</sub>Al bridges, which link the *o*-anisidine-derived fragments via the N centres. Within each *o*-anisidine-derived fragment, a four coordinate pseudo tetrahedral Me<sub>2</sub>Al group bridges the OMe and N centres; all aluminium atoms exhibited marked departures from ideal tetrahedral geometry with angles in the range 89.82(4) – 118.73(7) ° for Al(1) and 84.10(4) – 124.23(7) ° for Al(2). The Al – O bonds are typical of dative Lewis acid – base interactions (1.90 – 2.02 Å). [9]

**Figure 1.** Molecular structure of **1** showing the atom numbering scheme. Selected bond lengths (Å) and angles (°): Al(1) – N(1) 1.9454(11), Al(1) – N(1A) 1.9627(11), Al(2) – N(1) 1.9164(11), Al(2) – O(1) 1.9645(10); N(1) – Al(1) – N(1A) 89.82(4), N(1) – Al(1) – O(1) 84.10(4), Al(1) – N(1) – Al(1A) 90.17(4).

Similar use of *m*-anisidine failed to produce any crystalline product on cooling of a saturated toluene solution, instead it proved necessary to add an equal volume of *n*-hexane and cool the resulting toluene/hexane solution to -78 °C, whereupon a white crystalline product formed, albeit in much lower isolated yield (~ 21 %). Use of solely toluene tended to result in the formation of sticky (off-white) oil, which more often than not would fail to crystallize. The molecular structure of **2** is shown in Figure 2, with selected bond lengths and angles given in the caption. In contrast to complex **1**, the 1,3-deposition of the functional groups in the *m*-anisidine resulted in a centrosymmetric dimer which contains terminal Me<sub>3</sub>Al groups bound at the OMe function. The *m*-anisidine-derived fragments are linked via Me<sub>2</sub>Al bridges with retention of a NH group; the Al – N bridging bonds in **2** (*ca* 1.98 Å) are slightly longer than those in **1** (*ca* 1.95 Å).

An analogous product to **2** was obtained when employing *p*-anisidine as starting material, *viz* [*p*-(Me<sub>3</sub>AlOMe),NHC<sub>6</sub>H<sub>4</sub>(μ-Me<sub>2</sub>Al)]<sub>2</sub> (**3**), which can be readily recrystallized from a saturated toluene solution on prolonged standing at ambient temperature (isolated yield ~ 48 %).

**Figure 2.** Molecular structure of **2** showing the atom numbering scheme. Selected bond lengths (Å) and angles (°): Al(1) – O(1) 1.9600(13), Al(2) – N(1) 1.9802(15), Al(2) – N(1A) 1.9807(15); Al(1) – O(1) – C(6) 126.35(10), N(1) – Al(2) – N(1A) 87.67(6), Al(2) – N(1) – C(10) 119.57(9), Al(2) – N(1) – Al(2A) 92.34(6).

The molecular structure of **3** is shown in Figure 3, with selected bond lengths and angles given in the caption. The molecular arrangement of **3** is very similar to that present in **2**; a centrosymmetric dimer is formed from the two *p*-anisidine derived groups and two Me<sub>2</sub>Al bridges. The OMe function of each *p*-anisidine is bound to a terminal Me<sub>3</sub>Al group. The near rectangular Al<sub>2</sub>N<sub>2</sub> squares found in the cores in **2** and **3** are almost identical with Al – N bond lengths of *ca* 1.98 Å and angles of *ca* 88 ° and 92 °. By contrast, the Al<sub>2</sub>N<sub>2</sub> square in **1** has bond lengths of *ca* 1.96 Å with angles of *ca* 90 °, which more closely resembles the situation reported for the pyrrolyl-methylamide complexes {[C<sub>4</sub>H<sub>3</sub>N(2-CH<sub>2</sub>H*t*Bu)]AlH}<sub>2</sub> and {[C<sub>4</sub>H<sub>3</sub>N(2-CH<sub>2</sub>H*t*Bu)]Al(OCHMe<sub>2</sub>)<sub>2</sub>}. [10]

**Figure 3** Molecular structure of **3** showing the atom numbering scheme. Selected bond lengths (Å) and angles (°): Al(1) – O(1) 1.9582(19), Al(2) – N(1) 1.9851 (15), Al(2) – N(1A) 1.9809 (15); Al(1) – O(1) – C(6) 120.28(10), N(1) – Al(2) – N(1A) 87.24(6), Al(2) – N(1) – C(10) 120.62(14).

### Ring-Opening Polymerization (ROP) of $\epsilon$ -Caprolactone ( $\epsilon$ -CL).

Aluminium compounds are often reported as efficient catalysts for ring-opening polymerization (ROP) of cyclic esters. [1] The catalytic behaviour of **1** - **3** was explored toward the ROP of  $\epsilon$ -CL. Generally these complexes exhibited good activity for the ROP of  $\epsilon$ -CL. Runs were observed over 30 min, results for which are summarized in Table 1. Moreover, the detailed investigations for the optimization of the conditions were conducted by employing **1** as the initiator, the results for which are collected in Table 1.

The pre-catalyst **1** was effective in the ROP of  $\epsilon$ -CL both in the presence and absence of benzyl alcohol (BnOH) (Table 1, entries 6 and 7) though lower activities was observed in the absence of benzyl alcohol, although such conditions produced polymers with a similar molecular weight distribution. Given that the aluminium complex, in the presence of benzyl alcohol, exhibited better activity, detailed investigations of complex **1**-**3** have been carried out in the presence of BnOH (Table 1).

According to entries 1-5 in Table 1, a linear relationship between the monomer conversions and  $M_n$  values was observed with narrow molecular weight distributions [1.47-1.80], and a linear relationship between [CL]/[Al] ratio and number average molecular weight ( $M_n$ ), indicating the classical feature of a living polymerization process (Fig. 4 and Fig. 5). The molecular weight distributions [PDI] values of the resultant polymers became a little broader with increased monomer conversions [e.g., PDI: 1.47 (conversion 31.9 %), 1.41 (conversion 43.9 %), 1.73 (conversion 82.0 %), and 1.80 (conversion 98.7 %) in Table 1].

Table 1 displays result for elevation of the temperature (Table 1, entries 1-5), which resulted in higher molecular weight polymer and a higher conversion rate until 85 °C, and decreased at higher temperatures for **1**.

As high-molecular-weight polyesters possess better mechanical properties for subsequent utilization, high-molecular-weight PCL is an attractive target. An increase of the monomer/Al often leads to higher molecular weights; however, this is usually to the detriment of the monomer conversion rate. Here, we also investigated the effect of the  $\epsilon$ -CL/Al molar ratio on the catalytic

behaviour, and the results are given in Table 1 (entries 2, and 8-11). When the mole ratio CL: Al was increased from 62.5 to 1000, the molecular weight increased from  $0.53 \times 10^4$  to  $2.74 \times 10^4$  with little change of molecular weight distribution (1.88-1.98), but the conversion rate significantly decreased, producing polymers with lower molecular weight than the calculated  $M_n$  values (Figure. 5).

**Figure 4.**  $M_n$  and  $M_w/M_n$  vs. monomer conversion in the ROP of  $\epsilon$ -CL initiated by **1**/ *o*-anisidine aluminium complex (Table 1, entries 1-5).

**Figure 5.** Plots of  $M_n$  values vs. CL/Al molar ratio in the ROP of  $\epsilon$ -CL initiated by **1** (Table 1, entries 2, and 8-11).

<sup>a</sup> Conditions: 20  $\mu$ mol of cat.; 1.0 M  $\epsilon$ -CL toluene solution. <sup>b</sup> GPC data in THF vs polystyrene standards. <sup>c</sup> X = Al-anisidine complexes

In addition, we investigated the behaviour of the other complexes herein toward the ROP of  $\epsilon$ -CL. Generally, the anisidine aluminium complexes showed good catalytic activity with high conversion (> 90 %). The activity order **1** > **2**  $\approx$  **3** was observed, with **1** clearly outperforming **2** and **3** at 110 °C. The effect on the molecular weight of the polymer also exhibited the same order. Despite the similar conversion rates and molecular weights obtained using **2** and **3** at different temperatures (Table 2, entries 2, 3, 5, 6, 8 and 9), the molecular weight distributions using **3** were somewhat smaller, compared with **2** [e.g., PDI: 110 °C (1.73 vs 1.10), 85 °C (1.95 vs 1.37), and 25 °C (1.53 vs 1.16) in Table 2]. This is attributed to the ease with which **3** can be reproducibly crystallized on a large scale.

In order to compare the systems herein with others in the literature, we screened the complexes  $\text{Me}_2\text{Al}[\text{O}-2-t\text{Bu}-6-(\text{RN}=\text{CH})\text{C}_6\text{H}_3]$  (R = *t*Bu,  $\text{C}_6\text{F}_5$ ) under the same conditions. [2a,d] For R =  $\text{C}_6\text{F}_5$ , the system exhibited a conversion of 94.7 % at 60 °C over 60 min, whereas for R = *t*Bu, the systems was virtually inactive (conversion < 10 %) – see Table S1 (ESI). <sup>1</sup>H and <sup>13</sup>C NMR spectra of selected polymers (Table 2, entries 1 and 3) were obtained in order to verify the molecular weights of the polymer samples and to identify the end group present (see ESI, Figures S1 – S2). For entries using pre-catalyst **3** (and **2**), peaks at  $\delta$  7.37 ppm ( $\text{C}_6\text{H}_5\text{CH}_2-$ ), 5.15 ppm ( $\text{C}_6\text{H}_5\text{CH}_2-$ ), and 3.67 ppm ( $\text{CH}_2\text{CH}_2\text{OH}$ ) with an integral ratio of 5:2:2 for  $\text{H}_a$ ,  $\text{H}_b$ , and  $\text{H}_c$  indicate that the polymer chain is capped by a benzyl ester and a hydroxy end group, suggesting that the polymerization occurs through insertion of a benzyl alkoxy group into CL. However, for **1**, the peaks for the benzyl ester group end were absent, and the polymer chain is more likely capped with two hydroxy ends. <sup>13</sup>C NMR data also revealed peaks at  $\delta$  128.2 ppm ( $\text{C}_6\text{H}_5\text{CH}_2-$ ), 66.2 ppm ( $\text{C}_6\text{H}_5\text{CH}_2-$ ), and 62.6 ppm ( $\text{CH}_2\text{CH}_2\text{OH}$ ) assigned to the benzyl group for entries using pre-catalyst **3** (and for **2**). The molecular weight of PCL,  $M_n$  (NMR), was calculated based on the ratio between the integration of the peaks at 5.12 ( $\text{C}_6\text{H}_5\text{CH}_2-$ ) and 4.06 ( $\text{HOCH}_2\text{CH}_2-$ ). The MALDI TOF spectrum (see ESI, Fig. S4) of the PCL from **3** (and **2**) revealed the presence of benzyloxy initiating group and a series of peaks separated by 114.14 mass unit. By contrast, the MALDI for the PCL generated using **1** (see ESI, Fig. S3) was not consistent with the presence of any benzyloxy groups (this reflects the ability of **1** to catalyse the ROP of  $\epsilon$ -CL in the absence of BnOH).

### Ring-Opening Polymerization (ROP) of *rac*-Lactide (LA).

The ROP of *rac*-Lactide (LA) using **1–3** was conducted both in the presence and absence of BnOH. Disappointingly, these aluminium compounds exhibited very low activity (see Table. 3). <sup>1</sup>H NMR spectroscopic investigations were carried out in order to verify the molecular weights of the polymer samples and to identify the end group present. The results were similar to those obtained for the PCL runs; for the entry using pre-catalyst **3** (Table 3, entry 2), peaks at  $\delta$  7.36, 5.12 and 3.66 ppm (5:2:2) indicated that the polymer chains were capped by one benzyl ester and a hydroxy group, consistent with insertion of a benzyloxy group during polymerization. However, for the entry using pre-catalyst **1** (Table 3, entry 1), the spectra were consistent with a lack of benzyloxy groups (see ESI Fig. S5 – S7).

**Table 3.** Ring Opening Polymerization screening of *rac*-LA by pre-catalysts **1** to **3**.<sup>a</sup>

<sup>a</sup> Conditions: 20  $\mu$ mol of cat.; 1.0 M *rac*-LA toluene solution. <sup>b</sup> X = Al-anisidine complexes

In conclusion, we have treated *o*-, *m*- and *p*-anisidine each with two equivalents of trimethylaluminium. Crystal structure analyses of the products revealed that in the case of the *ortho*-anisidine, a complex containing two types of  $\text{Me}_2\text{Al}$  bridge is formed, namely  $\{[1,2-(\text{OMe})_2\text{N}-\text{C}_6\text{H}_4(\mu-\text{Me}_2\text{Al})](\mu-\text{Me}_2\text{Al})\}_2$  (**1**). By contrast, as a result of the increased distance between the methoxy and amino functionalities, both the *meta*- and *para*-anisidines react to form dimeric complexes containing an  $\text{Me}_3\text{Al}$  group bound to each

methoxy group, namely  $\{[1,3-(\text{Me}_3\text{AlOMe}),\text{NH}-\text{C}_6\text{H}_4](\mu\text{-Me}_2\text{Al})\}_2$  (**2**) and  $\{[1,4-(\text{Me}_3\text{AlOMe}),\text{NH}-\text{C}_6\text{H}_4](\mu\text{-Me}_2\text{Al})\}_2$  (**3**), respectively. In terms of the ROP of  $\epsilon$ -caprolactone, complexes **1** can efficiently promote the ROP of  $\epsilon$ -caprolactone both in the presence and absence of BnOH. Complex **1** afforded highest activity, particularly at 110 °C, and, given the molecular structures, this is tentatively attributed to the close proximity of the two  $\text{Me}_2\text{Al}$  bridging groups in **1**. It is noteworthy that we have previously observed beneficial cooperative

effects for two  $\text{Me}_2\text{Al}$  groups positioned 5.7818(10) Å apart in a macrocyclic system; [6] closer Al – Al interactions in such systems ( $< 3.2270(14)$  Å) hindered the polymerization process. Herein, the Al(1)  $\cdots$  Al(2) distance in the best performing system, namely the 'ortho' complex **1** is 3.394 Å, whereas in the 'meta' and 'para' complexes, the distance is somewhat shorter, for example in **2**, the Al(2) – Al(2A) distance is 2.8573(8) Å.

## Experimental

General: All manipulations were carried out under an atmosphere of dry nitrogen using conventional Schlenk and cannula techniques or in a conventional nitrogen-filled glove box. Toluene was refluxed over sodium. Acetonitrile were refluxed over calcium hydride. All solvents were distilled and degassed prior to use. IR spectra (nujol mulls, KBr windows) were recorded on a Nicolet Avatar 360 FT IR spectrometer; <sup>1</sup>H NMR spectra were recorded at room temperature

on a Varian VXR 400 S spectrometer at 400 MHz or a Gemini 300 NMR spectrometer or a Bruker Advance DPX-300 spectrometer at 300 MHz. <sup>1</sup>H NMR spectra were calibrated against the residual protio impurity of the deuterated solvent. Elemental analyses were performed by the elemental analysis service at the London Metropolitan University and Sichuan Normal University, Chengdu, Sichuan. The anisidine reagents were purchased from Sigma Aldrich and were used as received. Matrix Assisted Laser Desorption/Ionization-Time Of Flight (MALDI-TOF) mass spectrometry was

performed on Bruker autoflex III smart beam in linear mode. MALDI-TOF mass spectra were acquired by averaging at least 100 laser shots. 2,5-Dihydroxybenzoic acid was used as matrix and tetrahydrofuran as solvent. Sodium chloride was dissolved in methanol and used as the ionizing agent. Samples were prepared by mixing 20  $\mu$ l of polymer solution in tetrahydrofuran (2 mg/ml) with 20  $\mu$ l of matrix solution (10 mg/ml) and 1  $\mu$ l of a solution of ionizing agent (1 mg/ml). Then 1 ml of these mixtures was deposited on a target plate and allowed to dry in air at room temperature.

**Synthesis of {[1,2-(OMe),N-C<sub>6</sub>H<sub>4</sub>( $\mu$ -Me<sub>2</sub>Al)]( $\mu$ -Me<sub>2</sub>Al)}<sub>2</sub> (**1**)**  
Me<sub>3</sub>Al (16.5 ml, 1.0 M in toluene, 16.5 mmol) was added slowly to *o*-anisidine (0.92 ml, 8.1 mmol) at ambient temperature. The system was then refluxed for 12 h, and allowed to cool to room temperature. On prolonged standing (1 – 2 days), crystals of **1** formed, yield: 1.47 g, 77 %; further crops of crystals can be obtained from the mother liquor on prolonged standing at 0 °C. C<sub>22</sub>H<sub>38</sub>Al<sub>4</sub>N<sub>2</sub>O<sub>2</sub> Calcd: C 56.2, H 8.1, N 6.0. Found: C 55.9, H 8.0, N, 6.1 % IR: 1599w, 1574w, 1307w, 1277m, 1218s, 1198s, 1156s, 1109s, 1036w, 1006s, 921w, 854s, 772m, 756m, 722s, 647m. Mass spec (EI, positive mode): 471 M<sup>+</sup>, 456 M<sup>+</sup> - CH<sub>3</sub>, 426 M<sup>+</sup> - 2CH<sub>3</sub>, 399 M<sup>+</sup> - Al(CH<sub>3</sub>)<sub>2</sub>, 384 M<sup>+</sup> - Al(CH<sub>3</sub>)<sub>2</sub> - CH<sub>3</sub>. <sup>1</sup>H NMR (400 MHz, C<sub>6</sub>D<sub>6</sub>, 298 K)  $\delta$ : 6.98 – 6.80 (overlapping m, 8H, arylH), 3.76, 3.73 (2x s, 6H, OMe), -0.98 (s, 12H, Me<sub>2</sub>Al). <sup>13</sup>C NMR (100 MHz, C<sub>6</sub>D<sub>6</sub>, 298K)  $\delta$ : 148.97, 148.78, 141.29, 140.68, 124.96, 121.18, 121.08, 110.94, 110.71 (all arylC), 56.8, 56.7 (2x OMe), -5.33, -8.85 (2x Me<sub>2</sub>Al).

**Synthesis of {[1,3-(Me<sub>3</sub>AlOMe),NH-C<sub>6</sub>H<sub>4</sub>]( $\mu$ -Me<sub>2</sub>Al)}<sub>2</sub> (**2**)**  
As for **1**, but using Me<sub>3</sub>Al (16.5 ml, 1.0 M in toluene, 16.5 mmol) and *m*-anisidine (0.92 ml, 8.2 mmol). On cooling, hexane (30 ml) was added to afford **2** as an off-white solid on prolonged cooling at -78 °C, isolated yield 0.41 g, 21 %. C<sub>24</sub>H<sub>46</sub>Al<sub>4</sub>N<sub>2</sub>O<sub>2</sub> (sample dried *in vacuo* for 12 h) Calcd: C 57.3, H 9.2, N 5.5 %. Found: C 56.3, H 9.2, N 4.8 %. IR: 3394w, 1622w, 1604w, 1496w, 1260s, 1204w, 1158w, 1092s, 1019s, 862w, 799s, 721w, 687w, 451w. Mass spec (solid, positive ASAP: APCI): 446 (MH<sup>+</sup> - Al(CH<sub>3</sub>)<sub>2</sub> - toluene), 430 (M<sup>+</sup> - Al(CH<sub>3</sub>)<sub>2</sub> - CH<sub>3</sub>), 388 M<sup>+</sup> - 2Al(CH<sub>3</sub>)<sub>2</sub>, 374 (M<sup>+</sup> - Al(CH<sub>3</sub>)<sub>2</sub> - Al(CH<sub>3</sub>)<sub>2</sub>). <sup>1</sup>H NMR ((400 MHz, C<sub>6</sub>D<sub>6</sub>, 298 K))  $\delta$ : 7.13 – 6.27 (overlapping m, 8H, arylH), 3.41, 3.39 (2x s, 6H, OMe), 3.27, 3.21 (2x s, 2H, NH), -0.39 (s, 18H, Me<sub>3</sub>Al), -0.49, 0.50 (2x s, 12H, Me<sub>2</sub>Al). <sup>13</sup>C NMR (100 MHz, C<sub>6</sub>D<sub>6</sub>, 298 K)  $\delta$ : 130.5, 130.4, 129.1, 128.3, 125.4, 118.7, 114.0, 113.8, 113.0 (9x arylC; others either coincident or hidden by solvent), 62.8 (OMe), -8.0 (Me<sub>3</sub>Al), -9.6 (Me<sub>2</sub>Al).

**Synthesis of {[1,4-(Me<sub>3</sub>AlOMe),NH-C<sub>6</sub>H<sub>4</sub>]( $\mu$ -Me<sub>2</sub>Al)}<sub>2</sub> (**3**)**  
As for **1**, but using but using Me<sub>3</sub>Al (16.5 ml, 1.0 M in toluene, 16.5 mmol) and *p*-anisidine (1.00 g, 8.2 mmol), and the resulting residue was extracted into acetonitrile (20 ml) to afford colourless crystals of **3**. MeCN, isolated yield 0.99 g, 48 %. For **3**•MeCN (648.7) Calcd: C 62.9, H 9.0, N 6.5 %. Found: C, 63.0, H 9.0, N 6.9 %. IR: 3259m, 1883w, 1602w, 1506s, 1344m, 1303w, 1257m, 1238s, 1198s, 1153s, 1104m, 1042w, 1014m, 975s, 934w, 860s, 831m, 808m, 765bs, 710bs, 627w. Mass spec (solid, positive ASAP: APCI): 501 (M - H)<sup>+</sup>, 449 (M - H - Al(CH<sub>3</sub>)<sub>2</sub>), 372 (M - H - 2Al(CH<sub>3</sub>)<sub>2</sub>). <sup>1</sup>H NMR (400 MHz, C<sub>6</sub>D<sub>6</sub>, 298 K)  $\delta$ : 6.53 – 6.32 (3x m, 8H, arylH), 3.15, 3.13 (2x s, 6H, OMe), 3.11, 3.07 (2x s, 2H, NH), -0.39 (s, 18H, Me<sub>3</sub>Al), -0.48, -0.51, -0.52 (3x s, 12H, Me<sub>2</sub>Al). <sup>13</sup>C NMR (100 MHz, C<sub>6</sub>D<sub>6</sub>, 298 K): the sample proved to be too insoluble in C<sub>6</sub>D<sub>6</sub> to obtain useful spectra; a 12 h acquisition in CDCl<sub>3</sub> allowed us to identify  $\delta$  63.17 (OMe), -8.58 (Me<sub>3</sub>Al), -9.67 (Me<sub>2</sub>Al).

**Ring opening polymerization.** Typical polymerization procedures in the presence of one equivalent of benzyl alcohol (Table 4, run 1) are as follows. A toluene solution of **3** (0.010 mmol, 1.0 mL toluene) and BnOH (0.010 mmol) were added into a Schlenk tube in the glove-box at room temperature. The solution was stirred for 2 min, and then  $\epsilon$ -caprolactone (2.5 mmol) along with 1.5 mL toluene was added to the solution. The reaction mixture was then placed into an oil bath pre-heated to the required temperature, and the solution was stirred for the prescribed time. The polymerization mixture was then quenched by addition of an excess of glacial acetic acid (0.2 mL) into the solution, and the resultant solution was then poured into methanol (200 mL). The resultant polymer was then collected on filter paper and was dried *in vacuo*.

## Crystallography

Crystal data for **1** and **2** were collected on a Bruker SMART 1000 CCD diffractometer using narrow slice 0.3°  $\omega$ -scans for **1**. Data were corrected for Lp effects and for absorption, based on repeated and symmetry equivalent reflections [11]. Crystal data for **3** were collected on a Stoe IPDS2 diffractometer using 1°  $\omega$ -scans. A face index correction was applied.

Structures were solved by direct methods and refined by full matrix least squares on  $F^2$  [12, 13]. H atoms were included in a riding model except for H(6) in **1**, H(1) in **3**, for which coordinates were freely refined. Hydrogen atom  $U_{iso}$  values were constrained to be 120 % of that of the carrier atom except for methyl, ammonium, and hydroxyl-H (150 %). [14]

CCDC 986715, 986716, and 986717 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via (please use the link below) by e-mailing [data\\_request@ccdc.cam.ac.uk](mailto:data_request@ccdc.cam.ac.uk), or by contacting: The Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK.
