Nanoflaky (Ni, Co, Mn) oxides have successfully grown on the surface of the  $\beta\text{-MnO}_2$  nanorod via a simple redox reaction.

1 **Preparation and Performance of  $\beta$ -MnO<sub>2</sub> nanorod @ nanoflake (Ni,**  
2 **Co, Mn) oxides with hierarchical mesoporous structure**

8 **Abstract:** The rational design and facile synthesis of transition metal oxides are  
9 necessary to improve their application in the supercapacitors. Herein three kinds of  
10 hierarchical mesoporous structure transition metal oxides, which are composed of a  
11  $\beta$ -MnO<sub>2</sub> nanorod core and one of three different nanosheet hybrid (Ni, Co, Mn) oxide  
12 shells, are facilely synthesized via a novel *in situ* nucleation and growth of transition  
13 metal oxides on the surface of the  $\beta$ -MnO<sub>2</sub> nanorod. The crystallographic analyses  
14 demonstrated that the three kinds of hybrid oxide shells are consisted of cobalt  
15 manganese oxide (CMO), nickel manganese oxide (NMO), and nickel cobalt  
16 manganese oxide (NCMO), respectively. These transition metal oxides are evaluated  
17 as electrodes for high performance supercapacitors (SCs). The results reveal that  
18  $\beta$ -MnO<sub>2</sub>@CMO exhibits still a good rate capability of 35% capacity retention even at  
19 20A g<sup>-1</sup>, while  $\beta$ -MnO<sub>2</sub>@NMO displays a high pseudocapacitance of 560 F g<sup>-1</sup> at 1 A  
20 g<sup>-1</sup>. However,  $\beta$ -MnO<sub>2</sub>@NCMO combined the advantages of both  $\beta$ -MnO<sub>2</sub>@CMO  
21 and  $\beta$ -MnO<sub>2</sub>@NMO, exhibits a high specific capacitance of 675 F g<sup>-1</sup> at 1 A g<sup>-1</sup> with

22 excellent rate performance (about 30% capacity retention at  $20\text{ A g}^{-1}$ ) and cycling  
23 stability (83% capacity retention after 3000 cycles). The improved electrochemical  
24 performance can be attributed to the unique hierarchical architecture and the  
25 synergistic effect of different components.

26 **Key words:** Supercapacitor; Composite materials; Transition metal oxides; Core-shell  
27 structure, Rate capability

## 28 **1. Introduction**

29 In recent years, advanced energy storage devices have been extensively researched  
30 with the fast growing demand for high-power applications.<sup>1</sup> Especially,  
31 supercapacitors (SCs) are considered to be an important renewable energy storage  
32 device due to their faster charge/discharge process, longer lifespan, higher reliability  
33 and lower maintenance cost.<sup>2, 3</sup> There are three major types of electrode materials  
34 reported for SCs, including carbonaceous materials, transition metal oxides or  
35 hydroxides, and conducting polymers.<sup>4</sup> Among those electrode materials, the  
36 transition metal oxide composite is a kind of promising compound to solve low  
37 specific capacitance for carbon-based materials and poor cycling stability for  
38 polymers.<sup>5</sup>

39 Among transition metal oxides, Ni, Co, and Mn oxides, have been extensively  
40 studied as promising candidates for SCs because of their variety of oxidation states  
41 for charge transfer and high mass density.<sup>6, 7</sup> For example,  $\text{MnO}_2$  has a high  
42 theoretical specific capacitance of about  $1370\text{ F g}^{-1}$ ,  $\text{Co}_3\text{O}_4$  has a theoretical specific  
43 capacitance of about  $890\text{ F g}^{-1}$ .<sup>8</sup> However, the  $\text{NiO}_2$  and  $\text{Co}_3\text{O}_4$  suffer from poor

44 capacity retention and rate capacity, and the specific capacitance of  $\text{MnO}_2$  is still  
45 limited due to the low conductivity ( $10^{-5}$  to  $10^{-6}$  S  $\text{cm}^{-1}$ ) and low diffusion coefficient  
46 of inserted cations.<sup>9, 10</sup> Undoubtedly, it has been reported that the rational design of  
47 transition metal oxide composite can provide a promising solution to achieve  
48 excellent supercapacitive performance due to the synergistic effects of different  
49 components, which can effectively improve the electrochemical performances of the  
50 materials.<sup>11</sup> Thus, to address these problems, one strategy is to design  $\text{MnO}_2$ -based  
51 composite oxides with highly conductive transition metal compounds. For example,  
52  $\text{NiCo}_2\text{O}_4@ \text{MnO}_2$  core-shell nanowire arrays reported by Xu et al. present an  
53 improved capacitance ( $3.31 \text{ F cm}^{-2}$  at  $2 \text{ mA cm}^{-2}$ ).<sup>12</sup> However, the  $\text{MnO}_2$  is generally  
54 designed as the shell among most of the  $\text{MnO}_2$ -based composite transition metal  
55 oxides, which is still low conductivity.<sup>13, 14, 15</sup> Even though, many scholars try to  
56 prepare  $\text{MnO}_2$  as the core of the composites, the shell covered on the surface of the  
57  $\text{MnO}_2$  may be not uniform.<sup>16, 17</sup>

58 In this work, a facile hydrothermal method has been designed to synthesize three  
59 hierarchical nanocomposites with a  $\beta\text{-MnO}_2$  nanorod core and hybrid nanosheet shell.  
60 As  $\text{KMnO}_4$  is reduced by low valence metal ions ( $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$ ) under the hydrothermal  
61 process, the resultant  $\text{MnO}_2$  and Ni-Co hydroxides are in situ nucleation on the  
62 surface of the  $\beta\text{-MnO}_2$  nanorods prepared as the template. The hybrid shell offers  
63 several advantages: one is that the  $\beta\text{-MnO}_2$ , with stable crystal structure in both  
64 nanosheet shells and cores can form a stable framework owing to its high surface  
65 areas and interconnected porous nanostructures which could better accommodate

66 structural changes;<sup>18, 19</sup> the other is that the NiO<sub>2</sub>, Co<sub>3</sub>O<sub>4</sub> or NiCo<sub>2</sub>O<sub>4</sub> embedded in the  
67 framework can improve the conductivity of the composites. Besides, the  
68 morphologies and electrochemical properties of the as-prepared three novel  
69 composites are discussed in details.

## 70 **2. Experiment**

### 71 **2.1. Sample synthesis**

72 All the reagents were of analytical grade and used without further purification. The  
73 template of  $\beta$ -MnO<sub>2</sub> nanorods was prepared as in Ref.<sup>20</sup>  $\beta$ -MnO<sub>2</sub>@CMO  
74 nanocomposites are synthesized in a simple process, 0.2 g of as-prepared  $\beta$ -MnO<sub>2</sub>  
75 nanorod was dispersed in 75 mL of deionized water and ultrasonic treatment for 30  
76 min, and then 0.2 g KMnO<sub>4</sub> and 1.2 g CoSO<sub>4</sub>·7H<sub>2</sub>O were added to form a  
77 homogeneous purple solution, followed by stirring for 1h. After that, the above  
78 solution was transferred into a Teflon-lined autoclave (100 ml), sealed and put in an  
79 electric oven at 120 °C for 12 h, and then cooled down to ambient temperature  
80 naturally. Finally, the precipitation was filtered, washed with distilled water, vacuum  
81 dried and then calcined at 350 °C for 2h in flowing argon at a ramping rate of 1 °C.  
82 The process of synthesis of  $\beta$ -MnO<sub>2</sub>@NMO, and  $\beta$ -MnO<sub>2</sub>@NCMO nanocomposites  
83 are the same as above route. The details are as follows: for  $\beta$ -MnO<sub>2</sub>@NMO, 1g  
84 NiSO<sub>4</sub>·6H<sub>2</sub>O, 0.2 g KMnO<sub>4</sub> and 0.2 g  $\beta$ -MnO<sub>2</sub> nanorods were mixed in 75 ml  
85 deionized water, then the mixture were maintained at 130 °C for 24h; while for  
86  $\beta$ -MnO<sub>2</sub>@NCMO, the designed amount of CoSO<sub>4</sub>·7H<sub>2</sub>O and NiSO<sub>4</sub>·6H<sub>2</sub>O were mixed  
87 with 0.2 g  $\beta$ -MnO<sub>2</sub> nanorods in 75 ml deionized water, and then maintained at 140 °C

88 for 12h.

## 89 **2.2. Physicochemical properties characterization**

90 The crystallographic analyses of samples were carried out by X-ray diffraction (XRD)  
91 (D/max-2550 Rigaku, Japan). Morphology of samples was characterized using  
92 field-emission scanning electron microscopy (FESEM Nova NanoSEM 230). The  
93 morphology and structure of the nanocomposites were further investigated by  
94 transmission electron microscopy (TEM) (JEM-2100F, JEOL). The specific surface  
95 area and pore structure of the samples were determined by N<sub>2</sub> adsorption/desorption  
96 isotherm at 77 K (JW-BK 112) after the prepared samples were degassed at 110 °C  
97 overnight.

## 98 **2.3. Electrochemical measurements**

99 The working electrodes were prepared by the mixed slurry containing active materials  
100 (80 wt%), acetylene black (10 wt%) and polyvinylidene fluoride (PVDF 10 wt%) in  
101 N-methyl-2-pyrrolidone (NMP). The slurry was painted onto a nickel mesh with the  
102 area of 1 cm<sup>2</sup> then dried and pressed. Electrochemical measurements were performed  
103 on an electrochemical workstation (VersaSTAT3, Princeton Applied Research, USA)  
104 by using a three-electrode mode in an aqueous KOH (6.0 M) with a nickel mesh and  
105 Hg/HgO as the counter and reference electrode.

## 106 **3. Results and discussion**

### 107 **3.1. Morphology and Structural Analysis**

108 The fabrication processes of the novel architectures are schematically illustrated in  
109 Figure 1(a)-(d). The β-MnO<sub>2</sub> nanorod provides a suitable template for homologous

110 MnO<sub>2</sub> nucleating and growing because the surface of the β-MnO<sub>2</sub> nanorod is  
 111 consisted of perfect crystals. Firstly, when the β-MnO<sub>2</sub> nanorod was added to the  
 112 mixed solution containing KMnO<sub>4</sub>, CoSO<sub>4</sub> and NiSO<sub>4</sub> or either one of the two low  
 113 valence sulfates and stirred, the mixed solution will be adsorbed on the surface of the  
 114 β-MnO<sub>2</sub> nanorod. Then, along with the occurrence of the redox reaction during the  
 115 hydrothermal process, the reduced product MnO<sub>2</sub> will be *in situ* nucleating on the  
 116 surface of the β-MnO<sub>2</sub> nanorod, and the metal ions (Ni<sup>2+</sup>, Co<sup>2+</sup>) can be oxidized, and  
 117 then their hydroxides will be nucleated followed by MnO<sub>2</sub>. Finally, those novel  
 118 architectures with hybrid nanosheet shells and a β-MnO<sub>2</sub> nanorod core are easily  
 119 formed via this simple hydrothermal method. Besides, in the redox reaction process,  
 120 the quantity of CoSO<sub>4</sub> and NiSO<sub>4</sub> can be controlled in any desired ratios within  
 121 certain ranges, and the corresponding products will be obviously different.

122

123

124 **Figure 1** Schematic illustration of the formation of nanoflaky Ni, Co, Mn composite  
 125 oxides *in situ* growing on the surface of the MnO<sub>2</sub> nanorod.

126 The morphology of the as-synthesized samples was examined with scanning  
127 electron microscopy (SEM). As shown in Figure 2(a-c), Co, Ni and Co-Ni hydroxides  
128 grow uniformly on the surface of  $\beta$ -MnO<sub>2</sub> templates in company with MnO<sub>2</sub>. The  
129 yield of the shell is so high that the  $\beta$ -MnO<sub>2</sub> nanorods with a smooth surface are not  
130 observed in the nanocomposites. Obviously, among all composite oxides, the slice of  
131 the hybrid shell for  $\beta$ -MnO<sub>2</sub>@CMO-precursor is the thickest and tightest. Besides, for  
132  $\beta$ -MnO<sub>2</sub>@NMO-precursor and  $\beta$ -MnO<sub>2</sub>@NCMO-precursor, the flower texture layer  
133 with highly porous structure is uniformly deposited on the surface of the  $\beta$ -MnO<sub>2</sub>  
134 nanorods. It also can be seen that the diameter of the  $\beta$ -MnO<sub>2</sub>@CMO-precursor is the  
135 least, the  $\beta$ -MnO<sub>2</sub>@NMO-precursor has the most abundant pores, and  
136  $\beta$ -MnO<sub>2</sub>@NCMO-precursor shows the largest pore size and diameter. In addition,  
137 these nanoflaky shells are not changed after high temperature annealing as shown in  
138 Figure 2(d-f). The stability of those architectures can probably be attributed to the  
139 crystal structure of  $\beta$ -MnO<sub>2</sub>, which has the most stable structure among all crystals of  
140 MnO<sub>2</sub>. As a typical example, the low-magnification SEM image of  $\beta$ -MnO<sub>2</sub>@CMO is  
141 displayed in Figure 2g, it can be seen that the nanocomposites represent uniform  
142 distribution. The  $\beta$ -MnO<sub>2</sub> nanorod templates are also displayed in Figure 2h, where  
143 the nanorods show a smooth surface and uniform diameter. The porous structures are  
144 characterized by BET measurements. As shown in Figure 2i, the nitrogen  
145 adsorption/desorption isotherms of all prepared samples are the combination of type II  
146 and IV according to the IUPAC classification. The  $\beta$ -MnO<sub>2</sub>@NMO possesses the  
147 highest BET surface area of 130.9 m<sup>2</sup> g<sup>-1</sup> with a pore volume of 0.293 cm<sup>3</sup> g<sup>-1</sup>. The

148 specific surface area and pore volume of  $\beta\text{-MnO}_2\text{@NCMO}$  are  $102\text{ m}^2\text{ g}^{-1}$  and  $0.216$   
 149  $\text{cm}^3\text{ g}^{-1}$ , respectively. Besides, the  $\beta\text{-MnO}_2\text{@CMO}$  also possesses a high BET surface  
 150 area are  $88.3\text{ m}^2\text{ g}^{-1}$  with a pore volume of  $0.185\text{ cm}^3\text{ g}^{-1}$ . The BJH pore size  
 151 distributions of  $\beta\text{-MnO}_2\text{@CMO}$ ,  $\beta\text{-MnO}_2\text{@NMO}$  and  $\beta\text{-MnO}_2\text{@NCMO}$  are shown in  
 152 Figure 2i insert. It can be found that the pore sizes of  $\beta\text{-MnO}_2\text{@CMO}$ ,  
 153  $\beta\text{-MnO}_2\text{@NMO}$  and  $\beta\text{-MnO}_2\text{@NCMO}$  are concentrated at  $7.0\text{ nm}$ ,  $5.5\text{ nm}$  and  $6.0\text{ nm}$ ,  
 154 respectively. Obviously, the pore size of  $\beta\text{-MnO}_2\text{@NCMO}$  is intermediate between  
 155 those of  $\beta\text{-MnO}_2\text{@CMO}$  and  $\beta\text{-MnO}_2\text{@NMO}$ .

156

157

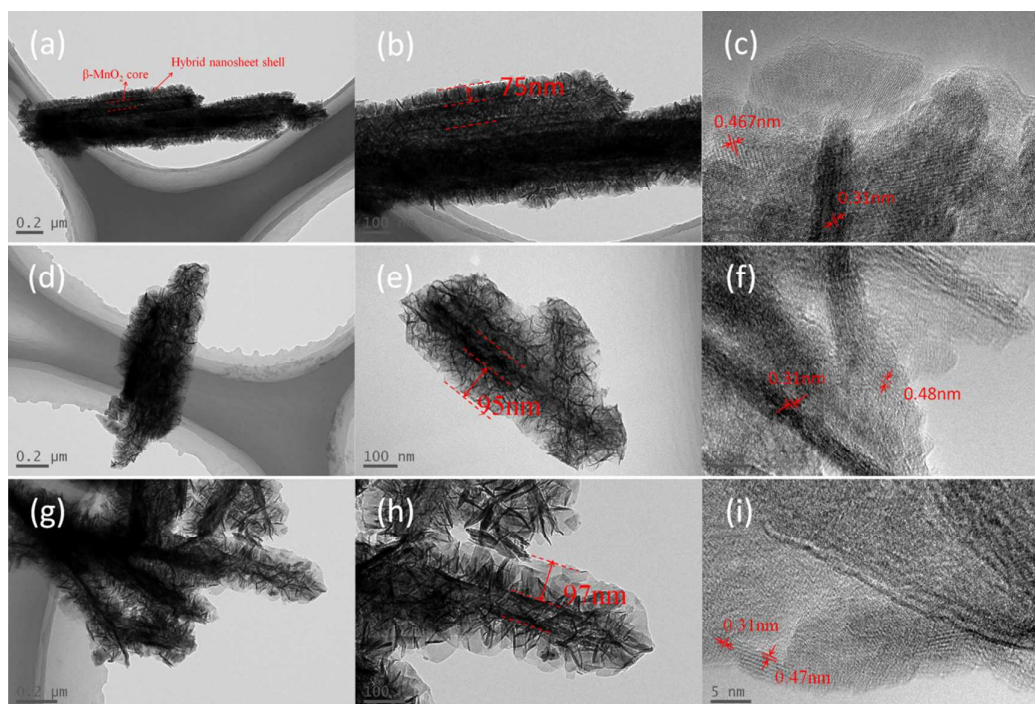

158

159 **Figure 2** SEM images of (a)  $\beta\text{-MnO}_2\text{@CMO}$ -precursor; (b)

160  $\beta$ -MnO<sub>2</sub>@NMO-precursor; (c)  $\beta$ -MnO<sub>2</sub>@NCMO-precursor; (d)  $\beta$ -MnO<sub>2</sub>@CMO; (e)  
161  $\beta$ -MnO<sub>2</sub>@NMO; (f)  $\beta$ -MnO<sub>2</sub>@ NCMO; (g) Low-magnification SEM image of  
162  $\beta$ -MnO<sub>2</sub>@CMO; (h)  $\beta$ -MnO<sub>2</sub> templates. (i) Nitrogen adsorption-desorption isotherms  
163 and pore-size distribution curves (inset) of the nanocomposites nanostructures.

164 The hierarchical hybrid structure is further illustrated from the TEM images from  
165 Figure 3. The low-magnification TEM images show that the surface of  $\beta$ -MnO<sub>2</sub>  
166 nanorods is uniformly covered with Ni, Co, Mn composite oxide nanosheets and  
167 formed a core-shell structure. In addition, the thickness of the different nanosheets  
168 and layers can be contrasted in the TEM images (Figure 3b, e, h). It can be found that  
169 the layers of the  $\beta$ -MnO<sub>2</sub>@CMO,  $\beta$ -MnO<sub>2</sub>@NMO and  $\beta$ -MnO<sub>2</sub>@NCMO are about 75  
170 nm, 95 nm and 97 nm thick, respectively. Besides, the slice of the  $\beta$ -MnO<sub>2</sub>@NMO is  
171 thinner than that of two others. The HR-TEM is used to investigate the lattice of  
172 surface layer hybrid metal oxide. The lattice spacing of 0.467 nm and 0.31 nm were  
173 observed in Figure 3c, which are in a good agreement with the theoretical interplanar  
174 spacing of Co<sub>3</sub>O<sub>4</sub> (111) and  $\beta$ -MnO<sub>2</sub> (110) planes. As shown in Figure 3(f, i), the  
175 interplanar spacing of 0.31 nm corresponds well to the (110) plane of  $\beta$ -MnO<sub>2</sub>, the  
176 0.48 nm and 0.47 nm can correspond to the (003) plane of NiO<sub>2</sub> and (111) plane of  
177 NiCo<sub>2</sub>O<sub>4</sub>, respectively. Therefore, it can be concluded that the shells of those  
178 nanocomposites are consisted of  $\beta$ -MnO<sub>2</sub> and Ni/Co composite oxides.

179

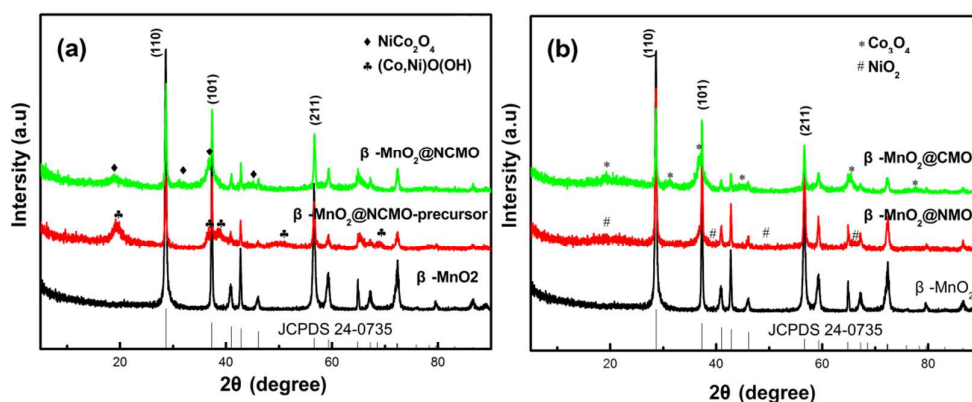

180

181 **Figure 3** Low-magnification and high-magnification TEM images of (a-c)182  $\beta$ -MnO<sub>2</sub>@CMO; (d-f)  $\beta$ -MnO<sub>2</sub>@NMO; (g-i)  $\beta$ -MnO<sub>2</sub>@NiCMO.

183 The crystallographic structures of the as-prepared  $\beta$ -MnO<sub>2</sub> nanorod,  
 184  $\beta$ -MnO<sub>2</sub>@NCMO-precursor and crystalline  $\beta$ -MnO<sub>2</sub>@NCMO nanocomposite  
 185 obtained by annealing the precursors at 350 °C for 2h were verified by XRD, as  
 186 shown in Figure 4a. The diffraction peaks of the MnO<sub>2</sub> nanorod represent all of the  
 187 characteristic peaks of pure pyrolusite-type MnO<sub>2</sub> (JCPDS 24-0735) phase without  
 188 any impurities. And the three broad diffraction peaks are located at around 29°,  
 189 37° and 57° in the XRD pattern of MnO<sub>2</sub>, which correspond to the diffraction bands  
 190 (110), (101) and (211) of  $\beta$ -MnO<sub>2</sub>, respectively. Besides, the diffraction peaks of  
 191  $\beta$ -MnO<sub>2</sub>@NCMO-precursor can be well indexed of (Co, Ni)O(OH) (JCPDS 29-0491)  
 192 apart from the dominant peak of  $\beta$ -MnO<sub>2</sub>. There is no contaminant detected,  
 193 indicating that the precursor is composed of  $\beta$ -MnO<sub>2</sub> and Ni-Co hydroxide. The

194 patterns of  $\beta$ -MnO<sub>2</sub>@NCMO reveal that the nickel cobalt oxide (NiCo<sub>2</sub>O<sub>4</sub>) (JCPDS  
 195 20-0781) can be found after the precursor was calcined at 350 °C for 2h. Furthermore,  
 196 Figure 4b shows that all the diffraction peaks are assigned to pure cobalt oxide (Co<sub>3</sub>O<sub>4</sub>)  
 197 (JCPDS 43-1003) and nickel oxide (NiO<sub>2</sub>) (JCPDS 85-1977) without any impurity  
 198 apart from  $\beta$ -MnO<sub>2</sub>.

199  
 200 **Figure 4** XRD patterns of (a)  $\beta$ -MnO<sub>2</sub>,  $\beta$ -MnO<sub>2</sub>@NCMO-precursor and crystalline  
 201  $\beta$ -MnO<sub>2</sub>@NCMO nanocomposites; (b)  $\beta$ -MnO<sub>2</sub>,  $\beta$ -MnO<sub>2</sub>@CMO and  $\beta$ -MnO<sub>2</sub>@NMO  
 202 nanocomposites.

### 203 3.2. Electrochemical Analysis

204 The supercapacitive performances of as-prepared products were evaluated by  
 205 electrochemical technology. Figure 5a shows the cyclic voltammograms (CVs) of  
 206  $\beta$ -MnO<sub>2</sub> nanorod and nanocomposite electrodes at a scan rate of 5 mV s<sup>-1</sup>. Clearly, a  
 207 pair of well-defined redox peaks within 0.1-0.5 V (vs. Hg/HgO) is visible in the CV  
 208 curve of the pure  $\beta$ -MnO<sub>2</sub>, which corresponds to redox couple of MnO<sub>2</sub>/MnOOM,  
 209 where M represents H<sup>+</sup> or K<sup>+</sup> ions.<sup>10</sup> Moreover, it can be seen that the three hybrid  
 210 nanocomposites have not only the redox peaks of MnO<sub>2</sub> but also a pair of redox peaks

211 within the -0.45-0.1 V (vs. Hg/HgO), which correspond to the reversible reaction of  
212  $\text{Co}^{3+}/\text{Co}^{4+}$  or  $\text{Ni}^{2+}/\text{Ni}^{3+}$  transitions associated with anions  $\text{OH}^-$ .<sup>21, 22</sup> It is obvious that  
213 the integrated area of  $\beta\text{-MnO}_2@\text{NCMO}$  in the current-potential curve is more than  
214 that of any others, and the increase of the CV integrated area will lead to a much more  
215 pseudocapacitance.<sup>23</sup> Thus, the  $\beta\text{-MnO}_2@\text{NCMO}$  gives a highest capacity. This may  
216 be ascribed to the synergistic effects of different components. Besides, it can be  
217 known from these CV curves that both the hybrid nanosheet shells and the  $\beta\text{-MnO}_2$   
218 core can contribute to the pseudocapacitance of nanocomposite.

219 Galvanostatic charge-discharge measurements were conducted between -0.45 to  
220 0.5 V (vs. Hg/HgO) at different current densities ranging from 1 to 20  $\text{A g}^{-1}$  to further  
221 evaluate the properties of the nanocomposites. As shown in Figure 5(b-d), it can be  
222 observed that there are two voltage plateaus at around -0.35 and 0.25. The specific  
223 capacitance is calculated by the formula,  $C = (I\Delta t)/(m\Delta V)$ , where  $I$  is the discharge  
224 current,  $\Delta t$  is the discharge time,  $\Delta V$  is the voltage range and  $m$  is the mass of the  
225 active material. The specific capacitance of  $\beta\text{-MnO}_2@\text{CMO}$  is as high as 437, 395,  
226 250, 200 and 149  $\text{F g}^{-1}$ ; for  $\beta\text{-MnO}_2@\text{NMO}$  is about 560, 510, 220, 132 and 70  $\text{F g}^{-1}$ ,  
227 and for  $\beta\text{-MnO}_2@\text{NCMO}$  is about 675, 593, 357, 254 and 190  $\text{F g}^{-1}$  at the current  
228 density of 1, 2, 5, 10, 20  $\text{A g}^{-1}$ , respectively. The specific capacitances of the three  
229 nanocomposite electrodes derived from the discharging curves at different current  
230 densities were compared, as shown in Figure 5e. The  $\beta\text{-MnO}_2@\text{CMO}$  electrode  
231 delivered a specific capacitance of 437  $\text{F g}^{-1}$  at the current density of 1  $\text{A g}^{-1}$ , which is  
232 lower than those of  $\beta\text{-MnO}_2@\text{NMO}$  and  $\beta\text{-MnO}_2@\text{NCMO}$  electrode. However, at the

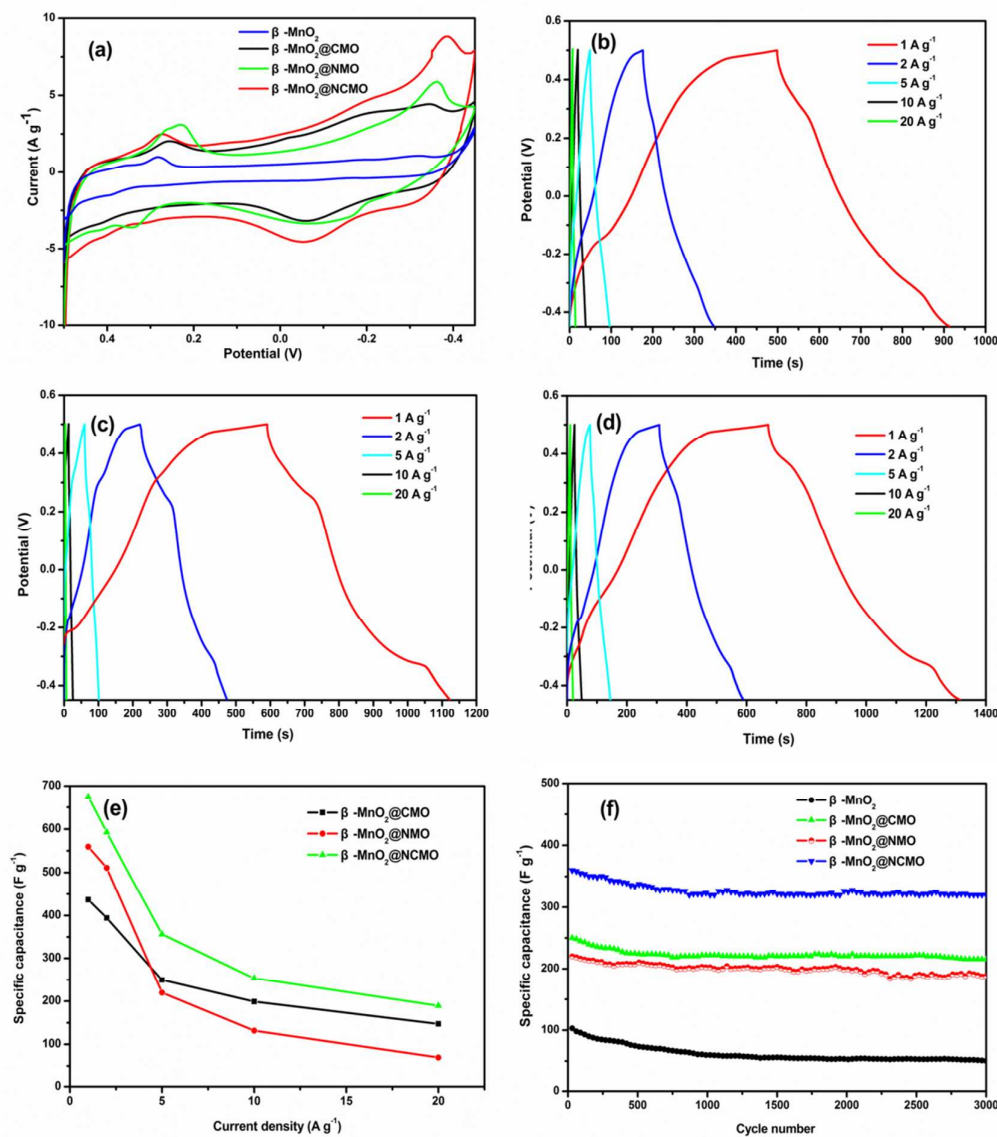

233 high current density of  $20 \text{ A g}^{-1}$ , the  $\beta\text{-MnO}_2\text{@CMO}$  electrode still delivered a high  
234 specific capacitance of  $149 \text{ F g}^{-1}$ , indicating much better rate capability compared to  
235 the  $\beta\text{-MnO}_2\text{@NMO}$  electrode which has a high specific capacitance of  $560 \text{ F g}^{-1}$  but  
236 decay fast to merely  $70 \text{ F g}^{-1}$  when the current density increased from  $1 \text{ A g}^{-1}$  to  $20 \text{ A}$   
237  $\text{g}^{-1}$ . It also can be seen clearly that the  $\beta\text{-MnO}_2\text{@NCMO}$  electrode exhibits best  
238 pseudocapacitance and rate capability among three nanocomposites.

239 The cycling stability of the nanocomposites and  $\beta\text{-MnO}_2$  nanorod electrodes are  
240 evaluated by the repeated charging-discharging measurement at constant current  
241 density of  $5 \text{ A g}^{-1}$ , as shown in Figure 5f. A significant specific capacitance loss can be  
242 seen for  $\beta\text{-MnO}_2$  nanorod electrode that only 51% of the initial capacitance is retained  
243 after 3000 cycles. While for  $\beta\text{-MnO}_2\text{@NMO}$  and  $\beta\text{-MnO}_2\text{@NCMO}$  electrodes, the  
244 specific capacitances are about 220 and  $360 \text{ F g}^{-1}$  in the 1<sup>st</sup> cycle, and remained 173  
245 and  $305 \text{ F g}^{-1}$  after 3000 cycles, the corresponding capacitance loss is 21% and 17%,  
246 respectively. In addition, the cycling stability of  $\beta\text{-MnO}_2\text{@CMO}$  is slightly better than  
247 that of the other two electrodes, which the capacitance loss is about 14% after 3000  
248 cycles. It can be known that the nanocomposite electrodes show a much better cycling  
249 stability than pure  $\beta\text{-MnO}_2$ .

250 The results reveal that  $\beta\text{-MnO}_2\text{@CMO}$  exhibits a good rate capability, while  
251  $\beta\text{-MnO}_2\text{@NMO}$  displays a high pseudocapacitance. These differences in  
252 performances can be mainly attributed to the morphological characteristics of the  
253 mesoporous and the nanosheets architectures, as well as the composition of  
254 constituents. Evidently, the mesoporous and nanosheets within those architectures can

255 provide more active sites and path for efficient electrolyte ions transportation.<sup>24</sup>  
256 Therefore, the fact that  $\beta\text{-MnO}_2\text{@NMO}$  displays a much higher pseudocapacitance  
257 can be dependent on its much higher BET surface area than  $\beta\text{-MnO}_2\text{@CMO}$ . Besides,  
258 compared with the other two nanocomposites electrodes,  $\beta\text{-MnO}_2\text{@CMO}$  exhibits the  
259 best rate capability. It may be attributed to its largest BJH pore sizes which can  
260 facilitate the diffusion of ions and improve charge accumulation. Moreover,  
261  $\beta\text{-MnO}_2\text{@NCMO}$  combines the advantages of both  $\beta\text{-MnO}_2\text{@CMO}$  and  
262  $\beta\text{-MnO}_2\text{@NMO}$ , exhibiting a high specific capacitance and cycling stability. Those  
263 good performances can be attributed to not only full utilization of individual  
264 constituents, but also a strong synergistic effect of different components. However,  
265 since the pure transition metal oxide composites still suffer from low conductivity,  
266 some efforts remain to be done to further improve the cycling performance and  
267 depress the capacity decay of  $\beta\text{-MnO}_2\text{@NCMO}$ , such as combination with high  
268 conductivity graphene, carbon or conducting polymer.

269

270 **Figure 5** (a) CV curves of as-synthesized samples at a scan rate of  $5 \text{ mV s}^{-1}$ ;

271 Constant-current charge-discharge profiles of (b)  $\beta\text{-MnO}_2\text{@CMO}$ , (c)

272  $\beta\text{-MnO}_2\text{@NMO}$ , and (d)  $\beta\text{-MnO}_2\text{@NCMO}$ ; (e) Specific capacitance of these

273 electrodes at various rates and (f) Cycling stability of as-synthesized samples at a

274 constant current density of  $5 \text{ A g}^{-1}$ .

275 Figure 6a shows the CV curves of  $\beta\text{-MnO}_2\text{@NCMO}$  at various scan rates of 5-40

276  $\text{mV s}^{-1}$ . It can be found that with the increase of the scan rate, the shapes of CV curves

277 show slight distortion and the areas surrounded by the CV curves are not significantly  
 278 influenced, implying good rate capability of the  $\beta$ -MnO<sub>2</sub>@NCMO electrode.  
 279 Electrochemical impedance spectroscopy (EIS) was further employed to detect the  
 280 properties of ion diffusion and electron transfer in the three kinds of nanocomposite  
 281 electrodes in the frequency range of 100 kHz to 10 mHz with an AC voltage of 5 mV.  
 282 The Nyquist plots are shown in Figure 6b and the inset shows the expanded plots at  
 283 high frequency region. The impedance spectra of three electrodes are almost similar in  
 284 form with a semicircle at the high frequency and an inclined line following at the low  
 285 frequency, which corresponds to the interfacial charge-transfer impedance and the  
 286 diffusive impedance of OH<sup>-</sup> ion within the electrode. The slopes of the semicircle at  
 287 high frequency of the three electrodes are also almost the same, indicating nearly  
 288 equal value of charge-transfer impedance. The diffusive impedance of OH<sup>-</sup> ion  
 289 within the  $\beta$ -MnO<sub>2</sub>@CMO and  $\beta$ -MnO<sub>2</sub>@NCMO are much lower than that of  
 290  $\beta$ -MnO<sub>2</sub>@NMO.

291  
 292 **Figure 6** (a) The CV curves of the  $\beta$ -MnO<sub>2</sub>@NCMO at different scan rates; (b)  
 293 Nyquist plots for the three nanocomposite electrodes, the inset is the expanded plots at  
 294 high frequency region.

#### 295 **4. Conclusion**

296 Accompanying with the formation of MnO<sub>2</sub>, the nanoflaky Co<sub>3</sub>O<sub>4</sub>, NiO<sub>2</sub> and NiCo<sub>2</sub>O<sub>4</sub>  
297 have successfully grown on the surface of the β-MnO<sub>2</sub> nanorod via a simple redox  
298 reaction between KMnO<sub>4</sub> and Co<sup>2+</sup>/Ni<sup>2+</sup> during a hydrothermal process. The  
299 electrochemical properties of these three hybrid nanostructured composites are  
300 evaluated as electrode materials for SCs and all of them show good electrochemical  
301 performance. Especially, the β-MnO<sub>2</sub>@NCMO, which has a good rate capability  
302 (about 30% capacity retention at 20A g<sup>-1</sup>) and excellent pseudocapacitance (about 675  
303 F g<sup>-1</sup> at 1 A g<sup>-1</sup>), shows superior to both β-MnO<sub>2</sub>@CMO and β-MnO<sub>2</sub>@NMO which  
304 exhibit good rate capability (35% capacity retention at 20A g<sup>-1</sup>) and high specific  
305 capacitance (560 F g<sup>-1</sup> at 1 A g<sup>-1</sup>), respectively. In addition, due to the synergistic  
306 effect of different metal oxides, the nanocomposites show good cycle stability, which  
307 is evidently much better than that of pure β-MnO<sub>2</sub> (only 51% capacity retention after  
308 3000 cycles). Therefore, the hierarchical transition metal oxide composites will be a  
309 kind of promising electrode materials for the application of high performance SCs and  
310 other energy storage fields, e.g., electrocatalysis and Li-ion batteries.
