Received

DOI:

A coupled system for the photodegradation of Rhodamine B dye was realized using Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> composite as a photocatalyst under visible light irradiation. The Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> composite was prepared by a hydrothermal method and characterized by Fourier transform-infrared spectroscopy (FT-IR), X-ray diffraction (XRD), UV-vis diffuse reflectance spectroscopy (DRS), scanning electron microscopy (SEM) and transmission electron microscopy (TEM). Compared with pure g-C<sub>3</sub>N<sub>4</sub>, Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> sample exhibits an enhanced photocatalytic activity and the best photocatalytic efficiency is 3.68 times more than that of pure g-C<sub>3</sub>N<sub>4</sub>. The obtained results indicate that coupled system of Bi<sub>2</sub>S<sub>3</sub> and g-C<sub>3</sub>N<sub>4</sub> could overcome the drawback of low photocatalytic efficiency brought by electron-hole recombination and narrow photoresponse range. On the basis of the corresponding energy band positions, the mechanism of photocatalytic activity enhancement was proposed.

## 1. Introduction

Recently, semiconductor-based photocatalyst has attracted much attention due to its potential employments in organic and inorganic pollutants remediation in wastewater, and water splitting for hydrogen production.<sup>1, 2</sup> Among numerous semiconductors reported, titanium dioxide (TiO<sub>2</sub>) is by far the most popular photocatalyst for its higher photocatalytic activity, good photostability, non-toxicity, and low price.<sup>3</sup> However, the most widely used TiO<sub>2</sub> photocatalyst is only active under UV irradiation (about 4% of solar photons can be used).<sup>4, 5</sup> To effectively eliminate electron-hole recombination in the photocatalytic reaction, many attempts have been made to improve the photocatalytic efficiency. Moreover, upon the viewpoint of utilizing solarlight, developing visible light response photocatalyst is more significant since 45% of the sunlight spectrum is visible light.<sup>6</sup>

Compared with traditional catalyst TiO<sub>2</sub>, graphitic-carbon nitride (g-C<sub>3</sub>N<sub>4</sub>) possesses a proper mid-wide band gap (2.7 eV) to absorb visible light efficiently.<sup>7</sup> Recent years, g-C<sub>3</sub>N<sub>4</sub> has drawn much attention for its high photocatalytic performance for

degradation ability of organic pollutants under visible light irradiation.<sup>8</sup> Unlike conventional organic semiconductor counterparts, g-C<sub>3</sub>N<sub>4</sub> exhibits a unique stability, including the heat endurance and chemical resistance. From reports, the as-prepared g-C<sub>3</sub>N<sub>4</sub> is non-volatile up to as high as 600 °C, and will be almost completely decomposed until the temperature rises to 700 °C<sup>9-11</sup> and chemical resistance emerged in that g-C<sub>3</sub>N<sub>4</sub> are almost insoluble in water, ethanol, toluene, diethyl ether and tetrahydrofuran.<sup>12</sup> The lone pair of nitrogen and electrons delocalization endows the tri-s-triazine derivatives, so g-C<sub>3</sub>N<sub>4</sub> with unique electronic structure, which is controllable due to their tunable band gap, and the excellent thermal and chemical stability<sup>13</sup> make it become one of the most promising semiconductor materials in the exciting research field.

According to the above, good performance seems to have endowed g-C<sub>3</sub>N<sub>4</sub> a bright future in the application of catalyst. Unfortunately, two main drawbacks of low separation efficiency of photogenerated electron-hole pairs and narrow visible light response range limit its practical application as an efficient visible-light photocatalyst.<sup>14, 15</sup> To improve photocatalytic efficiency, tremendous efforts have been made to improve the efficiency by doping with metal ions or non-metal ions, designing optimizing heterojunctions, and morphological modification. Research by Tian and coworkers showed that the g-C<sub>3</sub>N<sub>4</sub>/BiO<sub>4</sub> composite photocatalyst displays a higher photocatalytic activity than the two individuals, which can be attributed to its heterojunction structure.<sup>16</sup> Li and coworkers reported that

<sup>a</sup>School of Environment and Safety Engineering, Jiangsu University, 301 Xuefu Road, Zhenjiang, 212013, P R China

<sup>b</sup>School of Chemistry and Chemical Engineering, Jiangsu University, 301 Xuefu Road, Zhenjiang, 212013, P R China. E-mail: fxqiu@ujs.edu.cn; Fax: +86-51188791800; Tel: +86-51188791800

heterojunctions of graphitic carbon nitride (g-C<sub>3</sub>N<sub>4</sub>) and Bi<sub>2</sub>MoO<sub>6</sub> were synthesized by a hydrothermal method and the heterojunction composites exhibited higher photocatalytic activity than pure g-C<sub>3</sub>N<sub>4</sub> or Bi<sub>2</sub>MoO<sub>6</sub>.<sup>17</sup> Research by Theerthagiri showed that alpha-Fe<sub>2</sub>O<sub>3</sub>-g-C<sub>3</sub>N<sub>4</sub> composite photocatalysts of various compositions by a wet impregnation method and exhibited remarkably improved visible-light induced photocatalytic activity.<sup>18</sup>

To overcome the drawbacks of low photocatalytic efficiency brought by electron-hole recombination and narrow photoresponse range, it was proposed that g-C<sub>3</sub>N<sub>4</sub> could be coupled with narrow-band-gap semiconductor for enhancement of visible-light photocatalytic activity. In this study, bismuth sulfide (Bi<sub>2</sub>S<sub>3</sub>) with a narrow band gap of 1.3 eV was prepared and selected as modifier.<sup>19</sup> The photocatalytic activity evaluation was tested by the degradation of Rhodamine B (RhB) under visible light. The influence of Bi<sub>2</sub>S<sub>3</sub> on optical property and the photocatalytic activity of g-C<sub>3</sub>N<sub>4</sub> were studied. The influence of time on photocatalytic activity and the reaction kinetics of the composites were also investigated. The obtained results may provide an important indication that how to improve the photocatalytic activity under visible light, not only for g-C<sub>3</sub>N<sub>4</sub>, but also for the other photocatalysts. As far as we know, a novel Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> composite photocatalyst was designed and used for the degradation of organic pollutants for the first time.

## 2. Experimental section

### 2.1 Materials

Dicyandiamide (C<sub>2</sub>H<sub>4</sub>N<sub>4</sub>), ethylene glycol (HOCH<sub>2</sub>CH<sub>2</sub>OH, EG), thiourea (NH<sub>2</sub>CSNH<sub>2</sub>), bismuth nitrate pentahydrate (Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O), nitric acid (HNO<sub>3</sub>) and other reagents used in the experiments were obtained from Aladdin Chemical Reagent Co., Ltd. Deionized water was used throughout this study. All chemicals were of analytical grade and were used without further purification.

### 2.2. Preparation of g-C<sub>3</sub>N<sub>4</sub>

The graphitic-carbon nitride (g-C<sub>3</sub>N<sub>4</sub>) samples were prepared by directly heating dicyandiamide.<sup>4</sup> Typically, 2 g of dicyandiamide powder was put into a quartz crucible with a cover, then heated at a rate of 10 °C/min to reach a temperature of 600 °C; and then tempered at this temperature for 2 h in a flowing-nitrogen atmosphere. After the sample was cooled naturally to room temperature, the resulting powder was grinded in the agate mortar and used in subsequent studies.

### 2.3. Preparation of photocatalyst

In a typical procedure, 200 mg of g-C<sub>3</sub>N<sub>4</sub> was dissolved in 30 mL ethylene glycol under vigorous stirring for 20 min to get the dispersed solution, named solution A. A certain amount of Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O according to the designed mass ratio of Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O to g-C<sub>3</sub>N<sub>4</sub> was dissolved in diluted nitric acid to form a clear solution. Meanwhile, moderate thiourea was dissolved in 20 mL deionized water. After that, these two solutions were mixed together and the pH of this mixed solution was adjusted to 7 using certain amounts of NaOH solution, which was named solution B. Then, solution A and solution B were

mixed together and was stirred for 2 h. The obtained suspension was transferred into a 100 mL teflon-lined stainless steel autoclave up to 80% of the total volume, and then was heated to 160 °C and kept at this temperature for 24 h. After being cooled naturally to room temperature, the product was collected and washed using water and ethanol for 3 times, repeatedly, and dried at 60 °C for 12 h. The pure Bi<sub>2</sub>S<sub>3</sub> photocatalyst was obtained by the same conditions without adding g-C<sub>3</sub>N<sub>4</sub> powder. The process flow chart is illustrated in Scheme 1.

With the above method, a series of Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> composites with various amounts of Bi<sub>2</sub>S<sub>3</sub> were prepared according to different mass ratios of Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O to g-C<sub>3</sub>N<sub>4</sub>. The final products were named as Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-1, Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-2, Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-3, Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 and Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-5 samples, respectively (the mass ratios of Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O to g-C<sub>3</sub>N<sub>4</sub> were 10%, 20%, 30%, 40% and 50%, respectively). In addition, a catalyst with mass ratio of 40% (Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O to g-C<sub>3</sub>N<sub>4</sub>) was prepared by a simple mechanical mixing and named as Bi<sub>2</sub>S<sub>3</sub>&g-C<sub>3</sub>N<sub>4</sub>-4.

### 2.4. Characterizations

X-ray diffraction (XRD) patterns of samples were scanned on the Shimadzu LabX-6000 X-ray Diffractometer (40 kV, 30 mA) with a Cu K $\alpha$  radiation source at a scanning rate of 5°/min within the range of 5-90°. Fourier transform-infrared spectra (FT-IR) of all the catalysts (KBr pellets) were recorded on the equipment (AVATAR 360, Madison, Nicolet). UV-vis diffuse reflectance spectroscopy (DRS) was carried out on a Hitachi UV-3010 UV-vis spectrophotometer. BaSO<sub>4</sub> was as reference sample. Thermogravimetric analysis (TGA) was performed on a Netzsch STA 449C instrument (NETZSCH Corporation, Germany). The programmed heating range was from room temperature to 800 °C at a heating rate of 10 °C/min under air atmosphere. The measurement was taken with 6-10mg samples. The size and morphology of the nanoparticles were viewed on a PHI-Tecnaï 12 transmission electron microscope (TEM). High resolution transmission electron microscopy (HRTEM) was performed on the FEI-Tecnaï G2F30S-Twin transmission electron with a Philips CM200 field-emission gun microscope operating at 197 kV. The photocurrents were measured with an electrochemical analyzer (CHI660B, CHI Shanghai, Inc.). Photoluminescence (PL) spectra of the catalyst were measured on the QuantaMaster<sup>TM</sup> 40 (Photon Technology International, Inc.).

### 2.4. Photocatalytic activity

The photocatalytic activity of the photocatalyst was confirmed by the degradation of Rhodamine B (RhB) in an apparatus with a tungsten lamp (500 W) as the irradiation source. The visible-light ( $\lambda \geq 420$  nm) used in the present study was obtained by the filter with cut-off wavelength of 420 nm. Photocatalyst (50 mg) was dispersed into 100 mL RhB solution with the concentration of 5 mg/L, and then the mixture was stirred for 30 min in the dark to ensure absorption-desorption equilibrium, after which the reaction suspension was irradiated for 130 min under visible light. The temperature of the suspension was kept at about 25 °C by an external cooling jacket with recycled water. The samples were analyzed every 10 min by UV-vis spectrophotometer at maximum absorption characteristic peak of 553 nm (As shown in

Fig. S1, Supplementary Material). A linear calibration curve and correlation coefficient  $R^2=0.999$  are obtained over the range 0 to 5.0 mg/L (as shown in Fig. S2, Supplementary Material). Concentration at time  $t$  was generally labeled as  $C$ . The photocatalytic activity and degradation efficiency were calculated in the form of  $C/C_0$  and  $(C_0-C)/C_0$ , respectively. Where  $C_0$  (mg/L) is the initial concentration of RhB.  $C$  (mg/L) is the RhB concentration at time  $t$  (min).

### 3. Results and discussion

#### 3.1. Photocatalytic activity comparisons of photocatalysts prepared by mechanical mixing and hydrothermal method

The photocatalytic activity of RhB for blank experiment,  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 (Prepared by mechanical mixing method) and  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 (Prepared by hydrothermal method) samples were investigated (As shown in Fig. S3, Supplementary Material). From the obtained result, the photocatalytic activity of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 is bigger than that of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4. This is mainly because the composition of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4, prepared by the physically mixing, is easy to separate and could not form coupled system. So, series of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  photocatalysts were selected for the further study.

#### 3.2. XRD analysis

X-ray diffraction (XRD) studies were applied to study the phase, crystallinity and structure of the synthesized materials. XRD patterns of  $\text{g-C}_3\text{N}_4$  (a),  $\text{Bi}_2\text{S}_3$  (b) and  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 (c) samples are shown in Fig. 1. For  $\text{g-C}_3\text{N}_4$ , a strong peak at  $2\theta = 27.4^\circ$  marked with square is observed, which was corresponded to the characteristic interplanar staking peak (002) of aromatic systems.<sup>20</sup> For  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 sample, the intensity of the peak at  $2\theta = 27.4^\circ$  appears an enhancement compared with pure  $\text{Bi}_2\text{S}_3$ , due to the addition of  $\text{g-C}_3\text{N}_4$ . All other prominent peaks at  $2\theta = 22.19^\circ, 23.57^\circ, 24.95^\circ, 28.58^\circ, 31.72^\circ, 32.97^\circ, 33.85^\circ, 35.73^\circ, 39.96^\circ, 42.72^\circ, 45.48^\circ, 46.61^\circ, 52.53^\circ, 59.15^\circ, 62.55^\circ, 64.89^\circ, 67.60^\circ$  and  $69.31^\circ$  marked with circle, which were attributed to the (220), (101), (130), (211), (221), (301), (311), (240), (141), (421), (002), (431), (351), (242), (152), (721), (532) and (820) planes of  $\text{Bi}_2\text{S}_3$ , respectively (JCPDS 00-17-0320).<sup>21</sup>

#### 3.3. FT-IR analysis

The chemical structures of  $\text{g-C}_3\text{N}_4$  and  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  samples were analyzed by FT-IR and the results are shown in Fig. 2, from which it can be seen that the peaks at 1240, 1321, 1408, 1456, 1560 and 1641  $\text{cm}^{-1}$  are contributed to the typical stretching modes of CN heterocycles.<sup>22</sup> The absorption peaks near at 1560 and 1641  $\text{cm}^{-1}$  are corresponded to C=N stretching, while the peaks observed at 1240, 1321 and 1408  $\text{cm}^{-1}$  are attributed to aromatic C-N stretching.<sup>23</sup> The band around 806  $\text{cm}^{-1}$  is corresponded to the stretching vibrations of triazine ring.<sup>24</sup> A broad band near 3200  $\text{cm}^{-1}$  corresponds to the stretching vibration of O-H of the absorbed water molecule and the stretching modes of terminal  $\text{NH}_2$  groups at the defect sites of the aromatic ring.<sup>25</sup> It is worth noting that there were no differences of FT-IR peak between bulk  $\text{g-C}_3\text{N}_4$  and  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  samples,

from which it can be seen that the main characteristic peaks of  $\text{g-C}_3\text{N}_4$  appeared in all  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  photocatalysts. It is clear that the modification with  $\text{Bi}_2\text{S}_3$  does not alter the FT-IR absorption bands of the  $\text{g-C}_3\text{N}_4$  obviously.

#### 3.4. SEM and TEM analysis

To study the morphology of the as-prepared  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  sample, SEM micrographs of pure  $\text{g-C}_3\text{N}_4$ ,  $\text{Bi}_2\text{S}_3$  and  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 were taken, as shown in Fig. 3 (a), (b) and (c), respectively. As can be seen from Fig. 3 (a), pure  $\text{g-C}_3\text{N}_4$  is composed of big irregular particles with a diameter of micron size.<sup>20</sup> The morphology of pure  $\text{Bi}_2\text{S}_3$  is presented in Fig. 3 (b), showing monodisperse nanorods<sup>26</sup> with a diameter about 70 nm (seen as the inset of Fig. 3 (b)). Fig. 3 (c) shows the SEM morphology of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 composite. Different region exhibits the characteristic morphology of  $\text{g-C}_3\text{N}_4$ , and the similar morphology of  $\text{Bi}_2\text{S}_3$ . The corresponding EDS spectrum and result of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 are displayed in Fig. 3 (d). It can be seen that the  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 consists of C, N, Bi and S.

TEM and HRTEM were used to characterize morphology of the samples, and to identify the detailed crystallographic structure and orientation of the  $\text{Bi}_2\text{S}_3$  nanorod. Fig. 4 (a-c) showed typical TEM of pure  $\text{g-C}_3\text{N}_4$ ,  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 and amplification of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4. Compared with Fig. 4 (a), it can be seen clearly that the TEM of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -4 is different from that of pure  $\text{g-C}_3\text{N}_4$ . As seen in Fig. 4 (b), the structure of  $\text{Bi}_2\text{S}_3$  is exhibited as nanorods, which keep consistent with that shown in SEM. Fig. 4 (d) and (e) presented the HRTEM of  $\text{Bi}_2\text{S}_3$  nanorod, and clear fringe spacing with an interval of 0.36 nm could be indexed to (130) lattice plane of  $\text{Bi}_2\text{S}_3$ .<sup>22</sup> The crystallographic of  $\text{Bi}_2\text{S}_3$  is consistent with the result of XRD measurement.

#### 3.5. TG analysis

TGA experiments were carried out on NETZSCH STA449C with the heating rate 10  $^\circ\text{C}/\text{min}$  under air atmosphere. TG tests of single  $\text{Bi}_2\text{S}_3$ ,  $\text{g-C}_3\text{N}_4$  and all  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  samples were carried out; and TG curves are shown in Fig. 5. The first mass loss process is light from the room temperature to 200  $^\circ\text{C}$ , which is originating from the removal of adsorbed  $\text{O}_2$  and  $\text{H}_2\text{O}$ . From the curve of pure  $\text{g-C}_3\text{N}_4$ , it can be seen that the  $\text{g-C}_3\text{N}_4$  is fairly stable when the heat temperature is below 600  $^\circ\text{C}$ , and total weight loss is nearly 100% when the temperature is up to 750  $^\circ\text{C}$ , which implies that  $\text{g-C}_3\text{N}_4$  can decompose completely. From the  $\text{Bi}_2\text{S}_3$  curve, it becomes unstable when the temperature is above 280  $^\circ\text{C}$ . This may be due to that  $\text{Bi}_2\text{S}_3$  can decompose and transform into metal Bi, when the sample was heated about 400  $^\circ\text{C}$ . For single  $\text{Bi}_2\text{S}_3$ , the Bi content is calculated with the value of 81.3%. Compared with pure  $\text{g-C}_3\text{N}_4$ ,  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  samples become unstable when the temperature is above 280  $^\circ\text{C}$ . This is mainly because  $\text{Bi}_2\text{S}_3$  component was decomposed and transform into metal Bi in the former stage; and  $\text{g-C}_3\text{N}_4$  component of  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$  can decompose completely in the later stage when the temperature is up to 750  $^\circ\text{C}$ . The residual mass ratio increases with the increasing addition amount of  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ . For  $\text{Bi}_2\text{S}_3/\text{g-C}_3\text{N}_4$ -5 sample preparation process, the mass ratio of  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$  to  $\text{g-C}_3\text{N}_4$  is 50% and the metal Bi content in

Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-5 sample could be easily calculated with the value of 16.99%. As can be seen from Fig. 5 (a, b), the residual mass ratio is about 79.8 and 18.1% when the sample was heated over 750 °C. In consideration of small amount of impurity existing, the test result is according with the theoretical calculation value.

### 3.6. Optical properties

The UV-vis diffuse reflection spectra (DRS, A and B) of the pure g-C<sub>3</sub>N<sub>4</sub> (a), Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 (b) and Bi<sub>2</sub>S<sub>3</sub> (c) samples are shown in Fig. 6. From Fig. 6 (A), it can be seen that pure g-C<sub>3</sub>N<sub>4</sub> has photo-absorption not only in UV light range, but also in visible light range. But the absorption range is relatively narrow, which is less than 500 nm. It is worthy being noted that Bi<sub>2</sub>S<sub>3</sub> has strong absorption in nearly the whole range of visible light. Compared with pure g-C<sub>3</sub>N<sub>4</sub>, the light absorption ability of the composite is significantly enhanced after Bi<sub>2</sub>S<sub>3</sub> was introduced, which is attributed to the narrow band gap and large absorption coefficient of Bi<sub>2</sub>S<sub>3</sub>. As shown in Fig. 6 (B), the proposed band gap of Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 shifts to lower energy of 2.3 eV with the addition of Bi<sub>2</sub>S<sub>3</sub>. The band gap of pure g-C<sub>3</sub>N<sub>4</sub> (a) is about 2.7 eV, and which of Bi<sub>2</sub>S<sub>3</sub> (c) is about 1.3 eV. The results indicate that the introduction of Bi<sub>2</sub>S<sub>3</sub> generated an impurity band and narrowed the band gap of g-C<sub>3</sub>N<sub>4</sub>.

Furthermore, it is well known that semiconductors with intrinsic band gap structures possess reliable photoelectric properties related to efficient photo-electric conversion. Transient photocurrent responses for the pure g-C<sub>3</sub>N<sub>4</sub> (a) and Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 (b) were measured to supply an evidence to support that coupling Bi<sub>2</sub>S<sub>3</sub> played an important role in the photocatalytic reaction. From the results shown in Fig. 7, it can be seen that the transient photocurrent response of Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 (b) is much higher than that of pure g-C<sub>3</sub>N<sub>4</sub> (a), which is strong evidence that g-C<sub>3</sub>N<sub>4</sub> coupled with Bi<sub>2</sub>S<sub>3</sub>, the higher efficient separation efficiency of electron-hole pairs would achieve.

Table 1. Degradation efficiency and kinetics parameters for RhB degradation with Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>

Sample	RhB degradation efficiency (%)	First-order kinetics	
		Correlation coefficient (R <sup>2</sup> )	Apparent kinetic constant (k, min <sup>-1</sup> )
g-C <sub>3</sub> N <sub>4</sub>	26.61	0.992	0.00259
Bi <sub>2</sub> S <sub>3</sub> /g-C <sub>3</sub> N <sub>4</sub> -1	49.29	0.955	0.00571
Bi <sub>2</sub> S <sub>3</sub> /g-C <sub>3</sub> N <sub>4</sub> -2	61.45	0.948	0.00833
Bi <sub>2</sub> S <sub>3</sub> /g-C <sub>3</sub> N <sub>4</sub> -3	74.69	0.993	0.0111
Bi <sub>2</sub> S <sub>3</sub> /g-C <sub>3</sub> N <sub>4</sub> -4	98.10	0.985	0.0310
Bi <sub>2</sub> S <sub>3</sub> /g-C <sub>3</sub> N <sub>4</sub> -5	87.40	0.988	0.0148

### 3.7. Photocatalytic activity measurement

Photocatalytic activity of pure g-C<sub>3</sub>N<sub>4</sub> and Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> samples with variable Bi<sub>2</sub>S<sub>3</sub> amount were tested by degradation of RhB dye under visible light irradiation and the relative removal of RhB dye molecules in terms of irradiation time were shown in Fig. 8. From the results shown in Fig. 8, direct photolysis of RhB is almost negligible and bare g-C<sub>3</sub>N<sub>4</sub> showed a relatively low photocatalytic activity mainly through a photosensitive pathway, while RhB dye degradation efficiency is just 26.61%, as shown in Table 1. Bi<sub>2</sub>S<sub>3</sub> displayed a great impact on photocatalytic performance among all samples tested. With the increasing of Bi<sub>2</sub>S<sub>3</sub> amount, Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> samples display a dramatically enhancement upon identical conditions. Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 has a best photocatalytic activity with the degradation efficiency of 98.10%. However, Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-5 has a relative low photocatalytic activity, compared with Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4. It is probably because the larger Bi<sub>2</sub>S<sub>3</sub> leads to the agglomeration among nanoparticles, and leads to its decreasing photocatalytic activity (As shown in Fig. S4, Supplementary Material). The evolutions of absorption spectra of RhB in the presence of Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 under visible irradiation with different time are shown in Fig. S5 (Supplementary Material). It is clearly seen that the characteristic absorption band of RhB solution at 553 nm gradually diminishes in intensity with the increasing irradiation time. Moreover, no new absorption peaks appear, indicating the degradation of RhB and no other organic molecules generating. To clarify the final products after decomposition, the total organic carbon (TOC) values of residual RhB after the photodegradation of 5 mg/L RhB solution over Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 were measured (As shown in Fig. S6, Supplementary Material) and are obviously reduced within 130 min. The result indicates that RhB molecules have been decomposed into CO<sub>2</sub> and H<sub>2</sub>O.

The experimental data were fitted with a pseudo-first-order model to study reaction kinetics of RhB degradation. As shown in Fig. 9, the corresponding ln(C<sub>0</sub>/C) plot has a good linearity against time, indicating that the visible-light-driven photocatalytic degradation of RhB solutions in the presence of Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> follows the first-order kinetics. From Table 1, all tested samples display a good linearity and possess high correlation coefficient. Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub>-4 sample shows the largest reaction rate among all Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> samples that is nearly 12.0 times higher than that of pure g-C<sub>3</sub>N<sub>4</sub>.

### 3.8. Photocatalytic mechanism of Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> photocatalyst

To improve photogenerated carriers separation and enhance the efficiency of the interfacial charge transfer, one of the most valuable is to use two semiconductors in contact with different redox energy levels of conduction band (CB) and valence band (VB). In this study, g-C<sub>3</sub>N<sub>4</sub> was coupled with narrow-band-gap semiconductor (Bi<sub>2</sub>S<sub>3</sub>) for enhancement of visible-light photocatalytic activity. It is generally accepted that the relative positions of energy bands of g-C<sub>3</sub>N<sub>4</sub> (E<sub>VB</sub> = 1.57 eV, E<sub>CB</sub> = -1.13 eV)<sup>28</sup> and Bi<sub>2</sub>S<sub>3</sub> (E<sub>VB</sub> = 1.42 eV, E<sub>CB</sub> = 0.12 eV)<sup>19</sup> are shown in Scheme 2. When the Bi<sub>2</sub>S<sub>3</sub>/g-C<sub>3</sub>N<sub>4</sub> composites are irradiated under visible light, both g-C<sub>3</sub>N<sub>4</sub> and Bi<sub>2</sub>S<sub>3</sub> can easily absorb visible light and be excited to produce photogenerated electron-

hole pairs. The photogenerated holes ( $h^+$ ) in VB of  $g\text{-C}_3\text{N}_4$  and  $\text{Bi}_2\text{S}_3$  can directly oxidize RhB. The photogenerated electrons ( $e^-$ ) in CB of  $g\text{-C}_3\text{N}_4$  and  $\text{Bi}_2\text{S}_3$  can be captured by oxygen adsorbed on the surface of  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  composites to generate  $\bullet\text{O}_2^-$ , further to form  $\bullet\text{OH}$ , which would be responsible for the degradation of RhB.

According to the relative positions of energy bands, the photogenerated holes ( $h^+$ ) in VB of  $g\text{-C}_3\text{N}_4$  are easily transferred to  $\text{Bi}_2\text{S}_3$ . However, the photogenerated electrons in CB of  $g\text{-C}_3\text{N}_4$  are difficultly injected into  $\text{Bi}_2\text{S}_3$  because of the potential difference between CB of  $g\text{-C}_3\text{N}_4$  ( $-1.13$  eV) and  $\text{Bi}_2\text{S}_3$  ( $0.12$  eV).<sup>29, 30</sup> Due to  $g\text{-C}_3\text{N}_4$  coupled with  $\text{Bi}_2\text{S}_3$ ,  $h^+$  in VB of  $g\text{-C}_3\text{N}_4$  are easily transferred to  $\text{Bi}_2\text{S}_3$ , which is the main cause for the efficient separation of the photogenerated electron-hole pairs in  $g\text{-C}_3\text{N}_4$ . Hence, this coupled system effectively reduces the recombination of photoinduced electrons and holes, resulting in enhanced photodegradation efficiency of  $g\text{-C}_3\text{N}_4$ .

The photoluminescence (PL) spectrum is an effective approach to evaluate the separation capacity of the photogenerated charge carriers. In order to prove the effective separation of the photogenerated charges, PL spectra of  $g\text{-C}_3\text{N}_4$  (a),  $\text{Bi}_2\text{S}_3$  (b) and  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  (c) were shown in Fig. 10. The higher PL intensity means more efficient carriers participate in the recombination. On the contrary, the lower PL intensity means more carriers participate in photocatalytic process. As can be seen from Fig. 10 (a, b), there is a strong emission peak for  $g\text{-C}_3\text{N}_4$  and a relative low emission peak for  $\text{Bi}_2\text{S}_3$  at around 482 nm, which could be related to the recombination of the photoexcited electron-hole. However, PL intensity of  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  is lower than that of  $g\text{-C}_3\text{N}_4$  and  $\text{Bi}_2\text{S}_3$ , which suggests the improved charge carrier separation inside the composite.

### 3.9. Reusability studies

The reusability is an important parameter of the photocatalytic process. In order to examine the photocatalytic stability of the photocatalyst,  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  was selected for the recycling experiment and the result is shown in Fig. 11. As can be seen from Fig. 11 (A), the degradation efficiency of RhB is about 96.15% in the fifth run. Therefore, it can be concluded that the photocatalyst has good stability in the experimental conditions. The XRD patterns of  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  were examined further to verify durability before and after the photocatalytic reaction. As shown in Fig. 11 (B), the XRD patterns are almost identical, indicating that the sample is stable under light irradiation and has the ability to be reused.

### 4. Conclusions

In summary, visible-light-driven  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  composites were prepared by a hydrothermal method and studied as photocatalysts for degradation of RhB dye molecules. The photocatalytic activity of the composites increased then decreased with increasing  $\text{Bi}_2\text{S}_3$  content and  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  presents the best photocatalytic efficiency, which is more than 3.68 times that of pure  $g\text{-C}_3\text{N}_4$ . Moreover, from the study of reaction kinetics, it can be seen that  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  sample showed the largest reaction rate among all  $\text{Bi}_2\text{S}_3/g\text{-C}_3\text{N}_4$  samples which is nearly 12.0 times

higher than that of pure  $g\text{-C}_3\text{N}_4$ . On the basis of mechanism discussion, the enhanced activity is attributed to the coupled system which offers a wide response wavelength range and the effective separation of electron-holes pairs. Hence, this study has a guiding significance for the design of coupled system and has potential in environmental remediation applications.
