Reactivity of Uranium(III) with H₂E (E = S, Se, Te): Synthesis of a Series of Mononuclear and Dinuclear Uranium(IV) Hydrochalcogenido Complexes

Sebastian M. Franke,^{*a*} Michael W. Rosenzweig,^{*a*} Frank W. Heinemann,^{*a*} and Karsten Meyer^{*a**}

We report the syntheses, electronic properties, and molecular structures of a series of monoand dinuclear uranium(IV) hydrochalcogenide complexes supported by the sterically demanding but very flexible, single N-anchored tris(aryloxide) ligand (^{Ad}ArO)₃N)³⁻. The mononuclear complexes [((^{Ad}ArO)₃N)U(DME)(EH)] (E = S, Se, Te) can be obtained from the reaction of the uranium(III) starting material [((^{Ad}ArO)₃N)U^{III}(DME)] in DME *via* reduction of H₂E and the elimination of 0.5 equivalents of H₂. The dinuclear complexes [{((^{Ad}ArO)₃N)U₂(μ -EH)₂] can be obtained by dissolving their mononuclear counterparts in non-coordinating solvents such as benzene. In order to facilitate the work with the highly toxic gases, we created concentrated THF solutions that can be handled using simple glovebox techniques and can be stored at –35 °C for several weeks.

Introduction

Hydrochalcogenido complexes have received considerable interest in transition metal chemistry due to their potential applications as hydrodesulfurization and hydrogenation catalysts,¹⁻⁹ as well as their relevance in bioinorganic chemistry.^{1, 9-15} This class of compounds also serves as excellent precursors to a variety of homo- and heterobimetallic chalcogenido clusters with high nuclearity,9, 16-25 some of which exhibit interesting optical properties.^{26, 27} Furthermore, hydrochalcogenides have shown unusual reactivity such as Michaeltype addition reactions with activated alkenes to afford the respective thiolato complexes.^{19, 28, 29} In actinide chemistry, reports on chalcogenide complexes in general are rather scarce compared to the transition metals.³⁰⁻⁴⁸ Nevertheless, there has been a tremendous recent increase of interest in these types of compounds, which is motivated by the academic interest in synthesizing novel uraniumchalcogenide compounds and the fundamental importance of understanding the nature of covalent bonding between hard uranium ions and the soft chalcogenide ligands.⁴⁹⁻⁵² In contrast to their transition metal chemistry, heavier main group 6 hydrochalcogenides of the actinides are exceedingly rare. In fact, the only reported compound is the hydrosulfido complex $[(Cp^*)_3U(SH)]$ (Cp* = C₅Me₅) that has been synthesized by Spirlet et al. from H₂S or in a salt metathesis reaction from [(Cp*)₃U(Br)] and NaSH, but no crystallographic evidence was provided.53

Herein, we report the synthesis of the first series of uranium hydrochalcogenide complexes that can be obtained as mononuclear com-

plexes [((^{Ad}ArO)₃N)U(DME)(EH)] (**1-EH**, E = S, Se, Te) or as dinuclear complexes [{((^{Ad}ArO)₃N)U}₂(μ -EH)₂] (**2-EH**, E = S, Se, Te) depending on the choice of solvent (Chart 1). In this manner, either **1-EH** or **2-EH** can be synthesized from the uranium(III) starting material [((^{Ad}ArO)₃N)U(DME)] *via* reduction of H₂E and the elimination of 0.5 equivalents of H₂.

Results and Discussion

2 | J. Name., 2012, 00, 1-3

Recently, we reported the synthesis of the uranium(III) complex [((^{Ad}ArO)₃N)U(DME)] supported by the flexible, Nanchored chelator $(^{Ad}ArO)_3N^{3-}$ (with $(^{Ad}ArO)_3N^{3-}$ = tris(2hydroxy-3-adamantyl-5-methylbenzyl)amine).⁵⁴ This reactive, low-valent complex can undergo reactions such as the activation of CO2 and its heterocumulene analogs COS and CS_{2} , 55-57 as well as the activation of elemental chalcogens. 58 The starting material [((^{Ad}ArO)₃N)U(DME)] exhibits a halfstep potential of -1.879 V for the uranium(III/IV) redox couple, supporting the fact that this complex is a potent reductant, which - in part - explains its observed reactivity with the H₂E Furthermore, even uranium(IV) complexes substrates. supported by the (^{Ad}ArO)₃N³⁻ ligand can show remarkable reactivity under the right conditions, such as the formation of polychalcogenide complexes through stepwise addition of stoichiometrically precise amounts of elemental chalcogen.⁵⁹ H₂S and its heavier congeners H₂Se and H₂Te are known and well-documented precursors for the synthesis of hydrochalcogenides, however, the resultant hydrochalcogenides are rarely

stable compounds and subsequent reactions often lead to the formation of metal polychalcogenide clusters or binary metal salts instead.^{1, 9} Furthermore, synthetic work is greatly complicated by the high toxicity and malodor of these gases. With the commercial availability of H₂S as a solution in THF, reactions with this gas can be carried out under much simpler conditions. That said, no such reagents exist for its selenium and tellurium analogs. To solve these synthetic challenges, we created concentrated solutions of H₂Se and H₂Te by condensing the respective gas formed from Al₂E₃ (E = Se, Te) and sulfuric acid into a THF solution at $-70 \, ^{\circ}C.^{60}$ These solutions can be stored under an inert atmosphere in a freezer at $-35 \, ^{\circ}C$ for several weeks. This procedure greatly simplifies handling H₂Se and H₂Te.

Synthesis and molecular structures of mononuclear uranium(IV) hydrochalcogenido complexes 1-EH (E = S, Se, Te)

The mononuclear thiolato complex $[((^{Ad}ArO)_3N)U(DME)(SH)]$ (1-SH) could be synthesized by reacting the uranium(III) starting material $[((^{Ad}ArO)_3N)U(DME)]$ in THF with an excess amount of H₂S *via* dropwise addition of a solution of H₂S in THF until the reaction mixture turned green. Within five minutes, a light green precipitate formed and 1-SH was obtained in 70% yield after filtration and drying of the solids *in vacuo* (Scheme 1). Recrystallization of the solid *via* diffusion of *n*-hexane into a concentrated DME solution yielded crystals suitable for X-ray

Fig. 1 Molecular structures of uranium hydrosulfide complex 1-SH (left), uranium hydroselenide complex 1-SeH (center), and uranium hydrotelluride complex 1-TeH (right). The chalcogen-bound H atoms in 1-SH and 1-TeH could be located on the difference Fourier map, the proton in 1-SeH was placed in a position of optimized geometry. All other H atoms, the adamantyl groups, and co-crystallized solvent molecules are omitted for clarity. Thermal ellipsoids are at 50% probability.

diffraction analysis. The solid state structure of 1-SH reveals a mononuclear complex [((^{Ad}ArO)₃N)U(DME)(SH)] with a sevencoordinate uranium center in a distorted, monocapped trigonal prismatic coordination environment, in which one molecule of DME is coordinated to the uranium center in a bidentate fashion (Fig. 1,left). The U-S bond distance of 2.797(1) Å is clearly longer than reported U=S double bonds (2.382(11) - 2.481(1) Å) and is in good agreement with a U-S single bond (2.588(1) - 2.907(3) Å, Table 1).^{58, 59, 61-65} Furthermore, the chalcogen bound proton could be located in the difference Fourier map and was subsequently treated using a riding model. The U-N distance of 2.616(2) Å and the U-Oavg bonds of 2.171 Å are comparable to other complexes supported by the N-anchored ligand (AdArO)₃N^{3-54, 58, 59} Additionally, the SH⁻ ligand is not coordinated in the axial position directly trans to the nitrogen anchor, which is clearly shown in the N-U-S bond angle of 136.24(4)°.

Applying a similar synthetic procedure, the mononuclear selenolato complex $[((^{Ad}ArO)_3N)U(DME)(SeH)]$ (1-SeH) can be synthesized in 72% yield (Scheme 1). The molecular structure of 1-SeH, obtained from crystals grown from a concentrated DME solution, compares well to that of 1-SH (Fig. 1, center). Noteworthy, the asymmetric unit of the cell in 1-SeH contains two independent but structurally very similar molecules of the complex,

and hence, only the values of 1-SeH A are given in Table 1 (for more details see ESI). According to the 3σ criterion, the U-N (2.605(3) Å) and U–O_{avg.} bond lengths (2.170 Å) are the same as those observed in 1-SH. The U-Se bond of 2.936(1) Å is significantly longer than a distinctive U=Se double bond (2.533(1) -2.646(1) Å) and can be compared to other complexes with U-Se single bond distances varying from 2.719(1) to 3.125(1) Å.^{57-59, 61-63,} ^{66, 67} As in complex **1-SH**, the N–U–Se angle is strongly bent with 133.44(7)°. In contrast to 1-SH, the selenium-bound proton could not be located in the difference Fourier map, but was confirmed in ¹H and ²H{¹H} NMR experiments. The ¹H NMR spectrum of 1-SeH recorded in pyridine- d_5 shows a total of ten signals, ranging from -63 to 11 ppm, however, the unambiguous assignment of the proton peak of the SeH- ligand is severely hampered due to the complicated nature of the supporting ligand system. As a result, the deuterated analog of 1-SeH, namely [((^{Ad}ArO)₃N)U(DME)(SeD)] (1-SeD), was synthesized in a reaction of the uranium(III) starting material $[((^{Ad}ArO)_3N)U(DME)]$ with D₂Se. As expected, the ¹H NMR spectrum of 1-SeD shows only nine signals, and thus, unequivocally designates the signal at -62.86 ppm to the SeH⁻ proton. Additional ²H{¹H} NMR experiments in pyridine revealed a single deuterium signal at -62.69 ppm that originates from the SeD⁻ moiety, further supporting the previous assignment in the ¹H NMR

Scheme 2 Synthesis of dinuclear hydrochalcogenide complexes 2-EH (E = S, Se, Te).

spectrum and confirming the presence of the chalcogen-bound proton.

In contrast to the closely related syntheses of 1-SH and 1-SeH, the preparation of the tellurium analog complex [((^{Ad}ArO)₃N)U-(DME)(TeH)] (1-TeH), requires special precautions, since H₂Te is very susceptible to light and quickly decomposes at temperatures above 0 °C. As a consequence, the reaction needs to be carried out in cooled solvents under the rigorous exclusion of light to obtain 1-TeH in 78% yield (Scheme 1). Remarkably, the resulting complex 1-TeH is both stable at elevated temperatures up to 80 °C and in the presence of light, which contrasts with the very few reported, usually rather unstable, transition metal complexes featuring a TeH⁻ ligand.¹, Single crystals suitable for X-ray diffraction were obtained via diffusion of *n*-hexane into a mixture of benzene and DME (7:3). The molecular structure of 1-TeH is distinctly different from those of 1-SH and 1-SeH, as it shows a six-coordinate uranium center, located in a distorted octahedral coordination environment (Fig. 1, right). Furthermore, and consequently, the DME solvent molecule is now coordinated in a monodentate fashion. The U-N (2.575(1) Å) and U-O_{avg}. bond lengths (2.130 Å) are slightly shorter than those observed in 1-SH and 1-SeH. The U-Te bond distance of 3.122(1) Å is in accordance with the formulation of a U–Te single bond (Table 1).^{58, 61, 62, 67} The TeH⁻ ligand is coordinated almost linearly *trans* to the N-anchor in the axial position and shows a N– U–Te angle of 173.25(4)°. Attempts to obtain the hydroxo complex $[((^{Ad}ArO)_3N)U(DME)(OH)]$ from H₂O in the same way as complexes **1-EH** lead to the formation of the bridging oxo species $[\{((^{Ad}ArO)_3N)U(DME)\}_2(\mu-O)]$ instead, even in the presence of an excess amount of water. The rate of forming the hydroxo complex $[((^{Ad}ArO)_3N)U(DME)(OH)]$ appears to be much slower than the subsequent reaction to form $[\{((^{Ad}ArO)_3N)U(DME)\}_2(\mu-O)]$. The reason why H₂O reacts so slowly with the uranium(III) starting material may be ascribed to its high stability compared to the decreasingly stable hydrides of the heavier chalcogens.⁶⁸

Synthesis and molecular structures of dinuclear uranium(IV) hydrochalcogenido complexes 2-EH (E = S, Se, Te)

Interestingly, crystallization of 1-EH from non-coordinating solvents, such as benzene, leads to a change in coordination geometry. X-ray diffraction analysis on crystals grown from diffusion of *n*-hexane into saturated solutions of the complexes in benzene revealed the molecular structures of the dinuclear

Fig. 2 Molecular structures of uranium hydrosulfide complex **2-SH** (top), uranium hydroselenide complex **2-SeH** (bottom left), and uranium hydrotelluride complex **2-TeH** (bottom right). The chalcogen-bound H atoms in **2-SH** and **2-TeH** could be located on the difference Fourier map, the protons in **2-SeH** were placed in a position of optimized geometry. All other H atoms, the adamantyl groups and co-crystallized solvent molecules are omitted for clarity. Thermal ellipsoids are at 50% probability.

complexes $[\{((^{Ad}ArO)_3N)U\}_2(\mu-EH)_2]$ (E = S, 2-SH; Se, 2-SeH; Te, 2-TeH) (Scheme 2, Fig. 2). Each uranium center in 2-SH is now only six-coordinate and adopts a distorted octahedral coordination geometry. The U-S bond distances of 2.878(1) - 2.964(1) Å are slightly longer than in 1-SH and are significantly longer than those observed in the dinuclear bis-µ-sulfido complex [Na(DME)₃]₂- $[\{((^{Ad}ArO)_3N)U\}_2(\mu-S)_2]$ (2.688(2) - 2.714(2) Å) or the bridging persulfido complexes [{(R_2N)_3U}₂(μ - η^2 : η^2 - S_2)] ($R = SiMe_3, 2.706(2)$ -2.923(2) Å) and [{((SiMe₂NPh)₃tacn)U}₂(μ - η^{2} : η^{2} -S₂)] (2.855(2) -2.907(3) Å). $^{58,\;63,\;69}$ The SH $^-$ ligands with the shorter U–S distances are now coordinated in the axial positions trans to the nitrogen anchors, which is clearly visible in the N-U-S bond angles of 166.14(4)° and 166.63(4)°. The U-O_{avg.} (2.121 Å, 2.122 Å) and U-N bond distances (2.546(1) Å, 2.542(2) Å) are in good agreement with the respective structural parameters in complexes 1-EH (E = S, Se, Te). As in complexes 1-SH and 1-TeH, the chalcogen bound protons in complex 2-SH were located in the difference Fourier map.

The heavier chalcogenide complexes 2-SeH and 2-TeH exhibit the same molecular structures as 2-SH and feature comparable U-Oavg. and U-N bond lengths (see Table 1). The U-Se and U-Te bonds range from 2.989(1) to 3.094(1) Å and 3.119(2) to 3.296(2) Å, respectively, which is slightly longer compared to the bis-µchalcogenido complexes $[Na(DME)_3]_2[\{((^{Ad}ArO)_3N)U\}_2(\mu-E)_2]$ (E = Se, Te) (2.819 - 2.866 for E = Se and 3.031 - 3.112 for E = Te)and the bridging perselenido complex $[\{((^{Ad}ArO)_3N)U\}_2(\mu-\eta^2:\eta^2-\eta^2)]$ Se)(μ -DME)].^{58, 59} Furthermore, the N–U–E angles of 168.44(6)° and 169.00(6)° (2-SeH), as well as 171.00(7) ° and 166.68(10) °(2-TeH) are very similar compared to 2-SH but are slightly less bent due to a greater distance between the uranium centers $(d(U^{...}U) =$ 4.296 Å (2-SH) < 4.381 Å (2-SeH) < 4.448 Å (2-TeH)), which is in accordance with the larger atomic radii of selenium and tellurium that lead to slightly higher steric repulsion within the complexes. Noteworthy, the mononuclear complexes 1-EH and their dinuclear counterparts 2-EH showed identical ¹H NMR spectra in deuterated benzene. Complexes supported by the highly flexible N-anchored ligand (^{Ad}ArO)₃N³⁻ as well as the often highly nucleophilic EH⁻ functional groups show a strong tendency to form dinuclear species, hence, it is within expectation that 1-EH can dimerize to 2-EH in non-coordinating solvents, such as benzene, with the loss of coordinating solvent.^{1, 54-59} This conclusion is further supported by

the presence of broadened signals at approximately 3 ppm in all spectra, which is attributed to uncoordinated DME. Likewise, the dinuclear species **2-EH** can dissociate in DME to form the mononuclear complexes **1-EH**.

Infrared spectroscopy of complexes 1-EH and 2-EH

IR spectroscopy can be a useful tool to determine the presence of an EH group, since the characteristic, but often rather weak IR-active $v_{(E-H)}$ bands usually appear in the regions between $2300 - 2600 \text{ cm}^{-1} (\text{SH})$,⁷⁰⁻⁷⁶ $2200 - 2500 \text{ cm}^{-1} (\text{SeH})$,⁷⁴⁻⁸² and $1800 - 2000 \text{ cm}^{-1} (\text{TeH})$.^{74, 76, 83} However, complexes **1-SH** and **2-SH**, as well as **1-SeH**, **1-SeD** and **2-SeH**, do not show any $v_{(E-H)}$ bands at all, a fact that was also observed in several transition metal complexes.^{15, 18, 84-90} In contrast to this, complexes **1-TeH** and **2-TeH** both show one distinctive absorption band at 2000 cm⁻¹ and 1998 cm⁻¹, respectively, which is well in accordance with the scarce amount of data available for hydrotelluride complexes. Nevertheless, we could unambiguously identify the H atoms in all complexes **1-EH** and **2-EH** via X-ray diffraction analysis and ${}^{2}H{}^{1}H$ NMR spectroscopic experiments.

UV/vis/NIR spectroscopy of complexes 1-EH and 2-EH

The vis/NIR spectra of complexes 1-EH recorded in DME are all very similar and show a number of low intensity f-f transitions with small molar extinction coefficients of 10 - 35 $M^{-1}cm^{-1}$ between 500 and 2200 nm (see Fig. 3, left), characteristic for tetravalent complexes of uranium.91 While the spectra of 1-SH and 1-SeH are almost identical, the spectrum of 1-TeH clearly shows the hypsochromic shift of two bands at 1011 nm ($\varepsilon = 24 \text{ M}^{-1}\text{cm}^{-1}$) and 1815 nm ($\varepsilon = 20$ $M^{-1}cm^{-1}$). This observation can be rationalized by the discrepancy in the ligand-field splitting that should be expected due to the structural difference of 1-TeH compared to 1-SH and 1-SeH. The UV/vis region shows one intense charge-transfer band centered at 287 nm for each compound with molar extinction coefficients ranging from $14 - 19 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$ (see ESI, Fig. S25). The electronic absorption spectra of complexes 2-EH, recorded in benzene, are all very similar as well, showing very weak f–f transitions from 480 to 2000 nm ($\varepsilon = 5$ -

Fig. 3 Vis/NIR spectra of hydrochalcogenido complexes **1-SH** (9.2 mM, black), **1-SeH** (9.7 mM, red), and **1-TeH** (4.1 mM, blue) recorded in DME at 25 °C (left) and vis/NIR spectra of hydrochalcogenido complexes **2-SH** (2.0 mM, black), **2-SeH** (6.6 mM, red), and **2-TeH** (6.5 mM, blue) recorded in benzene at 25 °C (right). The molar absorption coefficients for complexes **2-EH** were calculated per uranium center for a better comparison.

Page 6 of 8

32 M⁻¹ cm⁻¹, Fig. 3, right) and intense charge-transfer absorptions centered at 284 nm in the UV/vis region ($\varepsilon = 12 - 12$ $14 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$, see ESI, Fig. S27). For a better comparison, the molar absorption coefficients for complexes 2-EH were calculated per uranium center, resulting in much lower values than those in complexes 1-EH. This observation is indicative of weaker U-E bonds and lower covalency and is further supported by the longer U-E bonds in the molecular structures of complexes 2-EH.^{92, 93} Furthermore, in contrast to complexes 1-EH, no hypsochromic shift was observed for any of the complexes 2-EH, however, 2-SH and 2-SeH exhibit an additional charge-transfer band at 395 and 406 nm, respectively (1-SH, $\varepsilon = 2185 \text{ M}^{-1}\text{cm}^{-1}$; 1-SeH, $\varepsilon = 2455 \text{ M}^{-1}\text{cm}^{-1}$), that could not be observed for 2-TeH. The spectra of compounds 1-EH and 2-EH are indicative for tetravalent uranium centers and are in contrast to the spectra anticipated for a U(V) 5f¹ or a U(III) 5f³ species.^{91, 94-97}

Magnetism of complexes 1-EH and 2-EH

The oxidation states and electronic structures of the uranium centers in complexes **1-EH** and **2-EH** (E = S, Se, Te) were further characterized by temperature-dependent magnetic susceptibility measurements. SQUID magnetization measurements from 2 – 300 K of compounds **1-EH** all reveal very similar magnetic moments of 2.56 (**1-SH**), 2.60 (**1-SeH**), and

Fig. 4 Temperature-dependent SQUID magnetization data of hydrochalcogenido complexes **1-EH** (top, E = S (black), Se (red), Te (blue)) and **2-EH** (bottom, E = S (black), Se (red), Te (blue)) as a plot of μ_{eff} vs. T. Data were corrected for underlying magnetism.

2.60 B.M. (1-TeH) at 300 K, which decrease with decreasing temperature to 0.30 (1-SH), 0.30 (1-SeH), and 0.26 B.M. (1-TeH) at 2 K (Fig. 4, top). Likewise, the dinuclear complexes 2-EH show magnetic moments of 2.46 (2-SH), 2.65 (2-SeH), and 2.44 B.M. (2-TeH) at 300 K that decrease to 0.34 (2-SH), 0.33 (2-SeH), and 0.31 B.M. (2-TeH) at 2 K (Fig. 4, bottom). These observations are in agreement with tetravalent uranium centers with a non-magnetic ³H₄ ground state.^{58, 98, 99} An interesting feature to note, is the difference in the plot of $\chi_{\rm M}$ vs. T of 1-EH and 2-EH. While the mononuclear complexes 1-EH show temperature-independent paramagnetism (TIP) over a wide temperature range from 10 to 62 K (for 1-SH and 1-SeH) and 101 K (1-TeH), followed by a steady decrease of the molar susceptibility, this feature is slightly less pronounced in the dinuclear complexes 2-SH and 2-SeH (TIP below 50 K, see ESI) and shows a significant difference in 2-TeH (TIP below 55 K).

Conclusion

The reaction of H_2E (E = S, Se, Te) with a reducing metal center is a viable synthetic route to obtain metal hydrochalcogenide complexes, however, handling of these gases is greatly complicated due to their high toxicity. With the use of concentrated and cooled solutions of these gases in THF, we were able to synthesize the new uranium(IV) hydrochalcogenido complexes $[((^{Ad}ArO)_3N)U(DME)(EH)]$ (1-EH, E = S, Se, Te), using simple glovebox techniques. These compounds yield the dinuclear complexes $[\{((^{Ad}ArO)_3N)U\}_2(\mu-EH)_2]$ (2-EH, E = S, Se, Te) in non-coordinating solvents, such as benzene, with the loss of coordinating DME. UV/vis/NIR spectroscopy and SQUID magnetization measurements further confirm that complexes 1-EH and 2-EH can be clearly distinguished both in solution and in the solid state. We are currently trying to access terminal mono-chalcogenido species from the herein presented hydrochalcogenido complexes, in order to establish a series of chalcogenido complexes with U-E single and U=E double bonds with similar coordination This series should provide an excellent environments. opportunity to gain more insight into the covalency and forbital participation of the U-E bond in uranium chalcogenido complexes.

Kilpatrick and Dr. Andreas Scheurer for performing ⁷⁷Se, ${}^{2}H{}^{1}H{}$ and COSY NMR experiments. We would also like to thank Dr. A. K. Abdul-Sada and Prof. Geoffrey N. Cloke for performing mass spectrometry experiments.
