TiO₂ nanofibers integrating space-separated magnetic nanoparticles and heterostructures have been fabricated to construct multifunctional photocatalysts with excellent photocatalytic activity and magnetic recoverability. Electrospinning technique has been employed to prepare the Fe₃O₄ embedded TiO₂ (Fe₃O₄@TiO₂) magnetic nanofibers. TiO₂/CdS heterostructures (Fe₃O₄@TiO₂/CdS) formed by depositing CdS nanoparticles on the Fe₃O₄@TiO₂ nanofibers have been obtained by a hydrothermal process. The heterostructures improve the photocatalytic activity and widen the range in solar light response. Under the visible light irradiation, photocatalytic activity of Fe₃O₄@TiO₂/CdS nanofibers is 5.11 times higher than that of Fe₃O₄@TiO₂ nanofibers, and is 1.22 times of CdS nanoparticles. And, it exhibits a slight increase under the simulated solar light with the photocatalytic degradation ratio of 1.1 times higher than that under visible light. The loading amounts of CdS only have effects on the photocatalytic activity under visible light and simulated solar light. Besides, the Fe₃O₄@TiO₂/CdS nanofiber exhibits the saturation magnetization strength of 1.572 emu g⁻¹, and can be effortlessly separated and recovered by applying a contactless magnetic field. The cycling stability is durable after the magnetic separation and recycling.

1 Introduction

TiO₂ nanofibers are fascinating fibrous morphology nanomaterials with many applications in environmental and energy issues, such as photocatalysts¹⁻³, Dye-sensitized solar cells (DSSC)⁴⁻⁶, Li-ion battery⁷⁻¹⁰ and membrane filtration¹¹. For applications in photocatalysis, the nanofiber morphology exhibits advantages in providing large external surface area and the inner space in the fiber to integrate functional components to construct efficient photocatalysts with high activity and recoverable separation for large scale water treatment. Electrospinning technique is a low-cost and convenient approach to fabricate the one-dimensional (1D) nanostructure and assemblies with hierarchical and core-shell structures¹²⁻¹⁴.

Magnetic TiO₂ nanofibers as heterogeneous photocatalysts are easily separated from the reaction solution system after utilization by applying a contactless magnet. The traditional strategy to endow TiO₂ nanofibers with magnetism is to decorate the surface of the nanofibers with iron-based magnetic compounds. CoFe₂O₄¹⁵ and Fe₃O₄¹⁶ are loaded on the surface of the nanofibers by combining electrospinning with co-precipitation or hydrothermal treatment. However, the external surface of the TiO₂ nanofiber as a photocatalyst is extremely important to the photocatalytic activity and the construction of hierarchical heterostructures. Thus, we need to embed the magnetic functional components into the nanofiber to form a core-shell structure. The one-step

electrospinning of a solution containing poly(vinyl pyrrolidone) (PVP) and alkoxide precursors of titanium and iron oxides is a direct method to achieve the embedded morphology. But, a direct contact between the embedded Fe₃O₄ and TiO₂ nanofiber would lead to the Fe³⁺-doped TiO₂ after the calcination, which has negative effects on the photocatalytic activity. An approach to resolve this problem is to coat the magnetic iron oxide nanoparticles with an isolating shell. Silica (SiO₂) is usually chosen as a versatile shell in the configuration of the core-shell structure. The extended Stöber method has been applied to fabricate a uniform and porous SiO₂ shell on magnetic Fe₃O₄ core¹⁷⁻¹⁹. This technique paves the way for constructing embedded magnetic Fe₃O₄ inside the TiO₂ nanofiber by direct electrospinning of the mixed dispersion of precursors, Fe₃O₄ with SiO₂ shell and PVP solution.

Heterostructures design on the surface of TiO₂ nanofibers is an effective means to improve the photocatalytic activity by forming heterojunctions. Semiconductors, plasmonic nanoparticles and photosensitive metal complexes are deposited or assembled on the TiO₂ nanofibers to form heterojunctions, such as SrTiO₃^{1a}, SnO₂²⁰⁻²², SnS₂²³, WO₃²⁴, Ba₄Ti₃O₁₂²⁵, CeO₂²⁶, In₂O₃²⁷, V₂O₅²⁸, Ag and Au nanoparticles^{29, 30} and copper (II) phthalocyanine³¹. CdS is a typical narrow band gap semiconductor with a band gap of 2.4 eV and a more negative conduction band (C.B.) electrochemical potential than that of TiO₂^{32, 33}. When the CdS/TiO₂ composite is exposed to the low energy photons of visible light, in principle, the electrons which are photo-excited to

the C.B. of CdS are transferred to that of TiO₂. Accordingly, the electrons and holes produced in CdS/TiO₂ heterostructure are separated and its spectrum response is extended to visible light, which could contribute to improve the catalytic activity.

5 Herein, we reported the fabrication of TiO₂ nanofibers integrating embedded magnetic Fe₃O₄ nanoparticles and TiO₂/CdS heterostructures as efficient photocatalysts with magnetic recoverability. The Fe₃O₄ embedded TiO₂ (Fe₃O₄@TiO₂) magnetic nanofibers were prepared through
10 electrospinning process combined with heat treatment at 753 K. The CdS nanoparticles were then deposited on the surface of Fe₃O₄@TiO₂ nanofibers (Fe₃O₄@TiO₂/CdS nanofiber) through a hydrothermal process. The XRD pattern shows that TiO₂ nanofibers are converted to anatase phase after heat treatment.
15 The characteristic SEM and TEM morphologies directly illustrate that the Fe₃O₄ nanoparticles are completely encapsulated in TiO₂ nanofibers with the CdS nanoparticles well dispersed on the surface. The UV-Vis diffuse reflectance spectra (UV-Vis DRS) show that the light absorption of Fe₃O₄@TiO₂/CdS nanofiber is
20 enhanced, and adsorption edge is extended to the visible spectrum range. The photocatalytic degradation ratio of Fe₃O₄@TiO₂/CdS-3 nanofibers for Rhodamine B (RhB) is 97.65% under UV irradiation, which is similar to the control sample of TiO₂ nanofibers with photocatalytic degradation ratio of 92.06% and
25 Fe₃O₄@TiO₂ nanofibers with the one of 97.86%. Under the visible light irradiation, photocatalytic activity of Fe₃O₄@TiO₂/CdS nanofibers is 5.11 times higher than that of Fe₃O₄@TiO₂ nanofibers, and is 1.22 times of CdS nanoparticles. And, it exhibits a slight increase under the simulated solar light
30 with the photocatalytic degradation ratio of 1.1 times higher than that under visible light. The loading amounts of CdS only have effects on the photocatalytic activity under visible light and simulated solar light. Besides, Fe₃O₄@TiO₂/CdS nanofibers exhibit strong magnetism and can be easily separated and
35 recovered by adding a contactless magnetic field. The cycling stability is durable after the magnetic separation and recycling.

2 Materials and Methods

2.1 Preparation of Fe₃O₄@SiO₂ core-shell structure

Fe₃O₄ nanoparticles were prepared by solution precipitation
40 according to the literature³⁴. FeCl₃·6H₂O (1.817g, analytic purity, Sonochemical Sinopharm Chemical Reagent Co., Ltd) was mixed with FeCl₂·4H₂O (1.113g, analytic purity, Sonochemical Sinopharm Chemical Reagent Co., Ltd) under N₂ atmosphere to react for 5 hours at 50 °C. After 0.5 hour, concentrated ammonia
45 (15ml, analytic purity, Sonochemical Sinopharm Chemical Reagent Co., Ltd) was added to precipitate the Fe₃O₄. For the preparation of Fe₃O₄@SiO₂, 0.4 g Fe₃O₄ was added in the mixed solution containing 80 mL absolute ethanol (analytic purity, Sonochemical Sinopharm Chemical Reagent Co., Ltd) and 20 mL
50 deionized water. After ultrasonic dispersion, 1mL of concentrated ammonia (28 wt%) was added into the solution. The mixed solution was stirred and, at the same time, 0.6 mL tetraethyl orthosilicate (analytic purity, Sonochemical Sinopharm Chemical Reagent Co., Ltd) and 5 mL absolute ethanol were added into the
55 mixed solution which was stirred constantly in the water bath at 30 °C for 8 h. The product was recovered with a magnet and

washed with deionized water and absolute ethanol three times, followed by drying at 80 for 2 h in vacuum oven.

2.2 Preparation of magnetic Fe₃O₄@TiO₂ nanofibers

60 1.5 g PVP (MW 1300000, Aladdin Chemistry Co. Ltd) was dissolved in 15 mL anhydrous ethanol (> 99 wt%) and stirred until the solution turned transparent. 0.1 g Fe₃O₄@SiO₂ nanoparticles were added into the above solution. After ultrasound treatment, the dispersion was intensively stirred for 24
65 h. The obtained dispersion was signed as A. 2 mL tetrabutyl ortho titanate was added dropwise into the mixed solution of 4 mL anhydrous ethanol and 4 mL acetic acid (99.5%). The mixed solution was stirred for 30 min, and the formed yellow solution named B. Solution B was slowly added into A and strongly
70 stirred for 4 h. The above gel was injected into a syringe of the self-made electrospinning apparatus with a copper electrode that inserted into the syringe. Then aluminum foil as cathode was placed in front of the nozzle with a distance of 20 cm and operated at 9 kV. After 10 h, a large fiber mat was produced.
75 After hydrolyzing completely in the air, the products were dried under vacuum at 80 °C for 4 h. The products were then heated in a muffle furnace with heating rate of 1 °C/min from room temperature to 480 °C and kept at 480 °C for 10 h to obtain Fe₃O₄@TiO₂ nanofibers.

2.3 Integrating TiO₂/CdS heterostructures on Fe₃O₄@TiO₂ nanofibers (Fe₃O₄@TiO₂/CdS)

The Fe₃O₄@TiO₂/CdS nanofibers were synthesized by a hydrothermal method. Three portions (each 0.050 g) of magnetic Fe₃O₄@TiO₂ nanofibers were added into the three reaction
85 solutions composed of 20 mL of deionized water (DI water), cadmium acetate and thiourea with the molar ratio of cadmium acetate and thiourea of 1:3, while the cadmium acetate are 0.1 mmol, 0.5 mmol and 0.8 mmol, respectively. The three solutions were transferred to Teflon-lined stainless autoclaves. The
90 hydrothermal treatment was conducted at 130 °C for 12 h and then cooled at room temperature. The magnetic products were collected by a magnet, and were washed with DI water and ethanol three times followed by drying at 80 °C for 12 h. The obtained products were denoted as Fe₃O₄@TiO₂/CdS-1,
95 Fe₃O₄@TiO₂/CdS-2, and Fe₃O₄@TiO₂/CdS-3 nanofibers.

2.4 Characterization

X-ray diffraction (XRD) patterns were recorded on a D8 Tool diffractometer using Cu Ka ($\lambda=0.15418$ nm). SEM images were performed on a JEOL JSM-6700F field emission scanning
100 electron microscope. The TEM images were observed on H-7650 transmission electron microscope operated at 120 kV. UV-Vis diffuse reflectance spectra (DRS) were recorded on a DWS 003 spectrophotometer. The magnetization curve was obtained on LaKe Shole7304 vibrating Sample Magnetometer (VSM). The
105 concentration of cadmium ion (Cd²⁺) in the solution was tested on a prodigy XP ICP-AES.

2.5 Adsorption and photocatalytic process

The photocatalytic activity was tested by examining the degradation of RhB in aqueous solution. The ultraviolet (UV)
110 light was illuminated by a 50 W high-pressure mercury lamp. Visible light and simulated solar light were illuminated by a Xe

lamp with UV cut-off filter and simulated solar light filter. Samples (0.010 g and 0.020 g) was added into 100 mL of the new prepared Rhodamine B (RhB) solution (1.0×10^{-5} mol L⁻¹) and stirred for 10 min at room temperature to obtain a good dispersion. Then, the system was kept in the dark to reach saturation adsorption for 1 hour. The irradiation started and the reaction system temperature was kept at 23 ± 3 °C by water cooling. After centrifugation to remove the photocatalyst, the concentration of RhB in the solution was measured by UV-Vis spectroscopy.

3. Results and discussion

The crystalline phase of the as-prepared samples was analyzed by powder X-ray diffraction (XRD). Fig.1 presents the XRD pattern of Fe₃O₄ nanoparticles, Fe₃O₄@TiO₂ nanofibers, and the CdS deposited Fe₃O₄@TiO₂ nanofibers (Fe₃O₄@TiO₂/CdS-2 nanofibers). All of the diffraction peaks in Fig. 1a can be indexed to the Fe₃O₄ structure (JCPDS 75-1609) which illustrate a high purity and crystallinity of the prepared Fe₃O₄ nanoparticles. As shown in Fig. 1b, the intensity of the Fe₃O₄ diffraction peaks weakens apparently and the identified peak at 25.4° is in good agreement with that of anatase TiO₂. The result in Fig. 1c shows the characteristic peaks of CdS at 26.80°, 28.08°, 43.90° and 52.20° (2θ), which is corresponded to (002), (101), (110) and (201) crystal faces and agreed with the standard peaks of hexagonal crystal of CdS (JCPDS 10-077-2306). According to the Scherrer equation, the average CdS particle size along (002) is 16.08 nm. Therefore, it is concluded that integration of magnetic nanoparticles and heterostructures on the Fe₃O₄@TiO₂/CdS nanofibers were successfully fabricated by the combination of an electrospinning technique with a hydrothermal synthesis.

Fig.1 XRD pattern of the electrospun TiO₂ nanofibers integrating space-separated magnetic Fe₃O₄ nanoparticles and TiO₂/CdS heterostructures. (a) Fe₃O₄ nanoparticles. (b) Fe₃O₄@TiO₂ nanofibers. (c) Fe₃O₄@TiO₂/CdS-2 nanofibers.

Magnetic nanoparticles and heterostructures space-separated morphology of the Fe₃O₄@TiO₂/CdS nanofibers with different CdS loading amounts was examined. Fig. 2 shows typical scanning electron microscopy (SEM) images. It can be clearly seen in Fig. 2a that the diameter of uniform nanofibers is in the

range of 150-200 nm. The surface of Fe₃O₄@TiO₂ nanofiber is relatively smooth with fiber lengths above 10 μm. The scanning electron microscope (SEM) images from Fig. 2b to Fig. 2d reveal that Fe₃O₄@TiO₂/CdS nanofibers are composed of numerous highly dispersed CdS nanoparticles with size of 15 nm attached onto the surface of the Fe₃O₄@TiO₂ nanofiber, thus resulting in the hierarchical heterostructures with a rough surface. To investigate the effects of CdS loading amounts on the photocatalytic activity, we have prepared Fe₃O₄@TiO₂/CdS nanofibers with different CdS loading amounts. As the concentrations of cadmium acetate and thiourea increase under the hydrothermal process, the loading amount of CdS on the Fe₃O₄@TiO₂ nanofiber increases. The results in Fig. 2c exhibit that when the amount of CdS reaches 59.1 wt%, the fibrous morphology is well retained with a little increase in the diameter due to CdS nanoparticles loading and with a rough surface. When the amount of CdS reaches 70.0 wt%, the loading density of CdS nanoparticles on nanofibers increases, and simultaneously the aggregation of CdS nanoparticles occurs, as shown in Fig. 2d.

Fig. 2 SEM images of the electrospun TiO₂ nanofibers integrating space-separated magnetic Fe₃O₄ nanoparticles and TiO₂/CdS heterostructure. (a) Fe₃O₄@TiO₂ nanofibers. (b) Fe₃O₄@TiO₂/CdS-1 nanofibers with CdS 22.4 wt%. (c) Fe₃O₄@TiO₂/CdS-2 nanofibers with CdS 59.1 wt%. (d) Fe₃O₄@TiO₂/CdS-3 nanofibers with CdS 70.0 wt%.

Fig.3 TEM images of the electrospun TiO₂ nanofibers integrating space-separated magnetic Fe₃O₄ nanoparticles and TiO₂/CdS heterostructures. (a) Fe₃O₄@TiO₂ nanofibers. (b) Fe₃O₄@TiO₂/CdS-2 nanofibers

Transmission electron microscopy (TEM) has been used to investigate the functional components space-separated morphology of the typical Fe₃O₄@TiO₂/CdS-2 nanofibers. As shown in Fig. 3a, it can be observed that the surface of the

nanofiber appears smooth, and $\text{Fe}_3\text{O}_4@/\text{SiO}_2$ nanoparticles were uniformly embedded in the nanofibers. The TEM images in Fig. 3b clearly show the rough surface of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers with small branches. They are the uniformly dispersed CdS nanoparticles, which is in accordance with the SEM image of Fig. 2c.

Fig. 4 shows the UV-Vis diffuse reflectance spectra (UV-Vis DRS) of the electrospun TiO_2 nanofibers with embedded magnetic Fe_3O_4 nanoparticles and surface CdS heterostructures. The light absorption of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers is extended to 510 nm, and the absorption edge shows an apparent red-shift. Moreover, its absorption intensity is enhanced by comparison with magnetic $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers. This result indicates that the photo-response range after CdS surface deposition is extended and photoabsorption ability is enhanced.

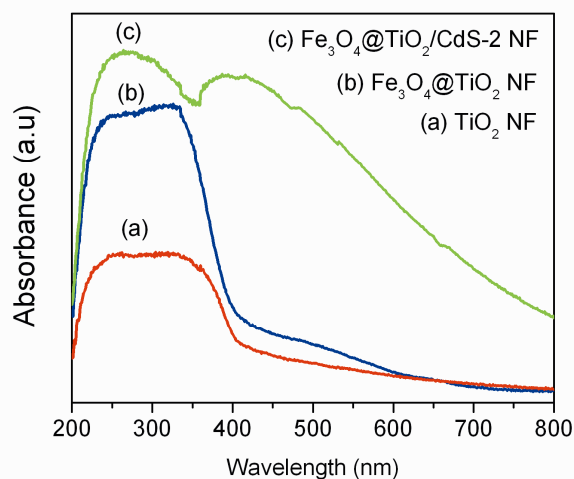

Fig.4 UV-Vis diffuse reflectance spectra (UV-Vis DRS) of the electrospun TiO_2 nanofibers integrating space-separated magnetic Fe_3O_4 nanoparticles and TiO_2/CdS heterostructures. (a) TiO_2 nanofibers (TiO_2 NF). (b) $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers ($\text{Fe}_3\text{O}_4@/\text{TiO}_2$ NF). (c) $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -2 nanofibers ($\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -2 NF).

Photocatalytic activities of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers with different CdS loading amounts were investigated through examining the degradation of RhB in aqueous solution (See Fig. S1, ESI[†]). The adsorption and photocatalytic activity of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers under UV light, visible light and simulated solar light were also examined by employing TiO_2 nanofibers, $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers and CdS nanoparticles as control to justify the contribution of heterostructures to the photocatalytic activity of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers. The results in Fig. 5a and Table 1 (See ESI[†]) show that the CdS on the surface of $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers has little effects on the increase of photocatalytic activity under UV irradiation. The photocatalytic degradation ratio of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -3 nanofibers for RhB is 97.65%, which is similar to the control sample of TiO_2 nanofibers with photocatalytic degradation ratio of 92.06% and $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers with the one of 97.86%. And, the variable CdS loading amounts for $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -1 and $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -2 nanofibers also exhibit little contribution to the photocatalytic activity under UV irradiation.

We consider that the reason would be ascribed to unexcited CdS under UV irradiation, and the photocatalytic activity is derived from TiO_2 nanofibers. To further investigate this

hypothesis, we carried out adsorption and photocatalytic experiments for $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers under visible light and simulated solar light by using CdS nanoparticles, $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers and TiO_2 nanofibers as control. The results in Fig. 5b show that the photocatalytic activity of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers is 5.11 times higher than that of $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers, and is 1.22 times of CdS nanoparticles. The increased photocatalytic activity of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers under visible light irradiation is ascribed to the heterojunctions between the TiO_2 nanofibers and CdS nanoparticles, which benefits the separation of excited holes and electrons. Besides, the photocatalytic degradation ratio of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers for RhB ascends from 71.27% to 90.25% as the loading amounts of CdS nanoparticles increases from 22.4wt% for $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -1 to 70.0 wt% for $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -3.

To further demonstrate the roles of heterostructures in improving the photocatalytic activity and widening the range of solar light response, we have also compared the activity of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ for degrading RhB solution under the irradiation of simulated solar light with that under visible light.

The Fig. 5c shows that the $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers as photocatalysts exhibit higher photocatalytic degradation ratio for RhB under simulated solar light irradiation. The photocatalytic activity of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers is 1.68 times higher than that of $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers, and is 1.36 times of CdS nanoparticles. Moreover, the photocatalytic degradation ratio of $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers for RhB ascends from 71.61% to 92.55% as the loading percent of CdS nanoparticles increases from 22.4wt% for $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -1 to 70.0 wt% for $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ -3. The photocatalytic degradation ratio of $\text{Fe}_3\text{O}_4@/\text{TiO}_2$ nanofibers for RhB is 3.6 times of that under visible light irradiation. In contrast with the CdS control, $\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$ nanofibers exhibit a slight increase in photocatalytic activity under the simulated solar light with photocatalytic degradation ratio of 1.1 times higher than that under visible light irradiation.

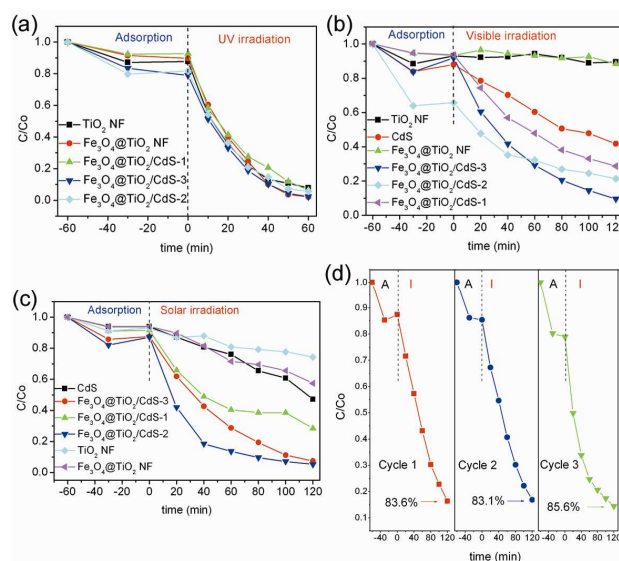

Fig.5 Adsorption and photocatalytic activity of the electrospun TiO_2 nanofibers integrating space-separated magnetic Fe_3O_4 nanoparticles and TiO_2/CdS heterostructure ($\text{Fe}_3\text{O}_4@/\text{TiO}_2/\text{CdS}$) for degradation of RhB.

Fe₃O₄@TiO₂/CdS-1 with CdS 22.4wt%, Fe₃O₄@TiO₂/CdS-2 with CdS 59.1wt% and Fe₃O₄@TiO₂/CdS-3 with CdS 70.0 wt%. (a) UV irradiation (High pressure Hg lamp) with TiO₂ nanofibers (TiO₂ NF), Fe₃O₄@TiO₂ nanofibers (Fe₃O₄@TiO₂ NF) as control. (b) Visible light irradiation (Xe lamp with visible light cut-off filter (>400 nm)) with CdS nanoparticles, TiO₂ nanofibers (TiO₂ NF), Fe₃O₄@TiO₂ nanofibers (Fe₃O₄@TiO₂ NF) as control. (c) Solar light irradiation (Xe lamp with simulated solar light filter) with CdS nanoparticles, TiO₂ nanofibers (TiO₂ NF), Fe₃O₄@TiO₂ nanofibers (Fe₃O₄@TiO₂ NF) as control. (d) Cycling stability of Fe₃O₄@TiO₂/CdS-3 NF under solar light irradiation (Xe lamp with simulated solar light filter) (A: adsorption and I: irradiation under solar light). The minus value in the time axis denotes the adsorption in the dark.

The cycling stability of Fe₃O₄@TiO₂/CdS nanofibers as a magnetically recoverable photocatalyst was also investigated. As shown in Fig. 5d, adsorption in the dark and photocatalytic activity under simulated solar light irradiation are retainable during the 3 cycles. But, photocatalytic degradation ratio of Fe₃O₄@TiO₂/CdS nanofibers for RhB decreases from 85.6% at 3th cycle to 61.8% at 5th cycle (See Fig. S2, ESI[†]).

As a concern that cadmium ion (Cd²⁺) would remain in the solution after the adsorption and photocatalytic process, we have checked the Cd²⁺ in the solution by ICP-AES after separating the powder photocatalysts with a high speed centrifugation. Under the same adsorption and irradiation conditions for the Fe₃O₄@TiO₂/CdS-3 nanofibers with CdS 70 wt% and the CdS control, The Cd²⁺ concentration (C_{Cd²⁺}) in the solution after adsorption and simulated solar light irradiation is 56.86 mg L⁻¹ for CdS control and 53.2 mg L⁻¹ for Fe₃O₄@TiO₂/CdS-3 nanofibers. Fortunately, the C_{Cd²⁺} in the solution declines during the following cycles, and it decreases to 9.7 mg L⁻¹ after the 4th cycle (See Fig. S3, ESI[†]).

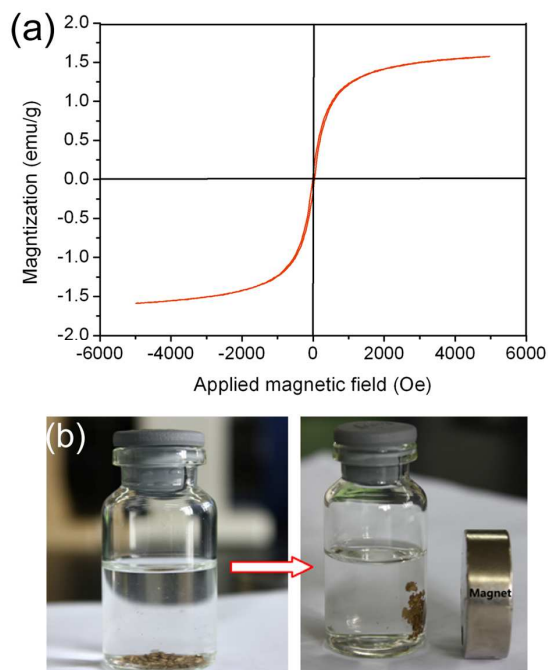

Fig.6 Magnetization and magnetic field induced separation and recoverability of Fe₃O₄@TiO₂/CdS nanofibers. (a) Magnetization curve of Fe₃O₄@TiO₂/CdS nanofibers. (b) Photo images of separation and recoverability of Fe₃O₄@TiO₂/CdS nanofibers by a contactless magnet.

Magnetization curve of Fe₃O₄@TiO₂/CdS nanofibers exhibits near-zero coercivity and remanence, suggesting a super

paramagnetic nature as shown in Fig. 6a. The saturation magnetization strength is 1.572 emu g⁻¹. It can be separated and recovered by applying a contactless magnetic field. As shown in Fig. 6b, the Fe₃O₄@TiO₂/CdS nanofibers were separated and collected from the solution with a magnet placed outside the bottle. Comparatively, the technology of contactless magnetic separation is easier to operate than the methods of traditional filter and centrifugal separation, and shows a promising potential in large scale industrial application.

Conclusions

In this work, anatase TiO₂ nanofibers integrating space-separated magnetic Fe₃O₄ nanoparticles and TiO₂/CdS heterostructures with magnetic recoverability and enhanced photocatalytic activity have been fabricated. Magnetic Fe₃O₄ nanoparticles with SiO₂ shells have been successfully embedded in the TiO₂ nanofiber (Fe₃O₄@TiO₂) through an electrospinning process. TiO₂/CdS heterostructures constructed by depositing CdS nanoparticles on the surface of Fe₃O₄@TiO₂ nanofiber has been formed through a hydrothermal process. The heterostructures increases the photocatalytic activity of the Fe₃O₄@TiO₂/CdS nanofibers, and the loading amounts of CdS nanoparticles only show positive effects on the photocatalytic activity under visible light and simulated solar light irradiation. The embedded magnetic Fe₃O₄ nanoparticles allow the integrated Fe₃O₄@TiO₂/CdS nanofibers to be effortlessly separated and recovered by applying a magnet. The strategy of integrating space-separated functional components on nanofibers provides a promising approach to design multifunctional components integration on fibrous morphology towards advanced photocatalysts with higher activity, effortless recoverability and durable recyclability.

Electrospun TiO₂ Nanofibers Integrating Space-separated Magnetic Nanoparticles and Heterostructures for Recoverable and Efficient Photocatalyst

Dahubaiyila, Xiaohui Wang, Xin Li, Baosharileadu, Xiaotian Li*, Liang Xu, Zongrui Liu,
Limei Duan* and Jinghai Liu *

TiO₂ nanofibers integrating space-separated magnetic Fe₃O₄ nanoparticles and TiO₂/CdS heterostructure (Fe₃O₄@TiO₂/CdS nanofiber) have been fabricated to construct multifunctional photocatalyst with excellent photocatalytic activity and magnetic recoverability. The heterostructures improve the photocatalytic activity and widen the range in solar light response. The loading amounts of CdS only have effects on the photocatalytic activity under visible light and simulated solar light. Besides, the Fe₃O₄@TiO₂/CdS nanofibers exhibit strong magnetism and can be effortlessly separated and recovered by applying a simple contactless magnetic field. The cycling stability is durable after the magnetic separation and recycling.
