**Abstract**

Canagliflozin is the first sodium-glucose co-transporter-2 inhibitor approved for the treatment of type 2 diabetes mellitus. In this study, a simple and sensitive HPLC assay with fluorescence detector was developed for accurate quantification of canagliflozin in human plasma using telmisartan as internal standard (IS). Plasma samples were extracted by liquid liquid extraction method using diethyl ether as an extracting solvent. Chromatographic separation of canagliflozin and IS was performed on Nucleodur Isis C<sub>18</sub> column with an isocratic mobile phase of 20mM potassium dihydrogen orthophosphate: acetonitrile (45:55, v/v) at a flow rate of 1 mL/min. Canagliflozin and IS were eluted at 2.8 and 5.8 min, respectively and detected at 280 and 325 nm for excitation and emission, respectively. The plasma calibration curve displayed excellent linearity over the concentration range of 16.13-6000 ng/mL. The assay was fully validated in terms of selectivity & specificity, linearity of calibration curve, accuracy & precision, recovery and stability in various storage conditions. To the best of our knowledge, this is the first validated HPLC-fluorescence detector assay for the quantification of canagliflozin in human plasma.

**Key words: Canagliflozin; HPLC; Fluorescence; Human plasma**

## 1. Introduction

Sodium-glucose co-transporter-2 (SGLT-2) inhibitor is a new class of oral antidiabetic drugs, which acts via insulin independent mechanism.<sup>1</sup> It produce effects by blocking the reabsorption of glucose from the proximal tubules of the kidney, leading to lowered renal threshold for glucose (RTG) and increased urinary glucose excretion.<sup>2,3</sup> Canagliflozin is the first SGLT-2 inhibitor which was approved in both USA and European countries for the treatment of type 2 diabetes patients.<sup>4,6</sup> It is highly selective to SGLT-2, and was found to be highly efficacious with good safety profile in clinical trials.<sup>3</sup> Being a novel mechanism of action, canagliflozin is not only suitable for monotherapy, but also in combination with other glucose-lowering agents, including insulin in patients who have not achieved glycemic targets with their initial therapies.<sup>7</sup>

The oral absorption of canagliflozin is rapid, with peak plasma concentrations achieved within 1-2 hours and steady-state levels within 4-5 days after once daily administration.<sup>3,4,8,9</sup> Absolute oral bioavailability of canagliflozin is 65%, with almost 99% bound to plasma protein, mainly albumin.<sup>10</sup> The reported terminal half-life ranged from 10.6-13.1 hours with a large volume of distribution, 119 L.<sup>9,11</sup> The *O*-glucuronidation is the main metabolic pathway for canagliflozin metabolism which produced two inactive metabolites via enzymes UGT1A9 and UGT2B4.<sup>4,12</sup>

A conducted literature search revealed only two reported assays for the analysis of canagliflozin. In the first reported technique, Devineni et al (2013) summarized the LC-MS/MS assay for the determination of canagliflozin in form of its ammonium adduct ion using electrospray ionization (ESI) in positive mode<sup>12</sup>. Recently we have also reported a UHPLC-MS/MS assay using ESI in negative mode for the determination of canagliflozin in rat plasma to

1  
2  
3 avoid adducts ion formation .<sup>13</sup> While the MS/MS could be advantageous in terms of sensitivity,  
4 selectivity and speed of analysis, but it would not be economical due to expensive  
5 instrumentation and the need for highly skilled technical expertise. Moreover, it is not usually  
6 available in most clinical, bioanalytical or educational research laboratories. So in a resource  
7 limited setting, a more convenient HPLC with UV or fluorescence detector (FLD) assays are  
8 usually preferred, provided lower limit of quantification (LLOQ) is sufficient for application.  
9 Additionally, HPLC-FLD assay allows more sensitivity compared to HPLC-UV assay.

10  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20 Considering the information mentioned above, herein, we aimed at developing a simple,  
21 reliable and economical HPLC-FLD assay, which enables easy determination of canagliflozin  
22 for routine analysis in all laboratories irrespective of whether they are equipped with  
23 sophisticated instruments or not. The developed assay was validated according to the USFDA  
24 and EMEA guideline.<sup>14,15</sup> The included validation parameters were selectivity, linearity and  
25 sensitivity, precision and accuracy, recovery, carryover effects and stability. The validation  
26 results were also compared with previously reported UHPLC-MS/MS assay and were  
27 successfully applied in incurred sample reanalysis.

## 2. Experimental

1  
2  
3 from Milli-QR Gradient A10R (Millipore, Mosheim Cedex, France) having pore size 0.22  $\mu\text{m}$ .  
4  
5 Blank EDTA human plasma was obtained from King Khalid University Hospital, Riyadh, Saudi  
6  
7  
8 Arabia.

9  
10 **2.2 Stock solution preparation.** Fresh standard stock solutions of canagliflozin (400  $\mu\text{g}/\text{mL}$ )  
11  
12 and IS (500  $\mu\text{g}/\text{mL}$ ) were prepared in methanol by dissolving accurately weighted amounts of  
13  
14 their pure materials. Separate stock solution of canagliflozin was prepared for calibration curve  
15  
16 and quality controls (QCs) samples from two separate weightings. All stock solutions were  
17  
18 stored in refrigerator at 4 $^{\circ}\text{C}$  temperature.  
19  
20

21  
22 **2.3 Calibration standards, QC and IS sample preparation.** A series of working standards for  
23  
24 calibration curve and QCs were prepared by further diluting of their respective stock solution  
25  
26 with acetonitrile: water (50:50, v/v). The plasma calibration standards of canagliflozin at eight  
27  
28 different concentration levels were prepared by spiking the 15  $\mu\text{L}$  of their respective working  
29  
30 standards in 150  $\mu\text{L}$  of plasma to obtain final concentration levels ranged 16.13-6000  $\text{ng}/\text{mL}$ .  
31  
32 Similarly four QCs, at 17.50, 50.0, 500 and 5000  $\text{ng}/\text{mL}$  were also prepared by spiking the 15  
33  
34  $\mu\text{L}$  of their respective working standards in blank plasma and treated as lower limit of  
35  
36 quantification for QC (LLOQ QC), low QC (LQC), mid QC (MQC) and high QC (HQC),  
37  
38 respectively. Both plasma standards and QC samples were kept at  $-80^{\circ}\text{C}$  until used during  
39  
40 validation and/or samples analysis. The IS working solution of 20  $\mu\text{g}/\text{mL}$  for routine use was  
41  
42 freshly prepared by diluting the IS stock solution in acetonitrile-water (50:50, v/v) and stored in  
43  
44 refrigerator.  
45  
46  
47  
48  
49

50  
51 **2.4 Instrumentation and Chromatographic conditions.** The analysis was performed on  
52  
53 Waters Alliance HPLC 2695 separation module connected to Waters 2475 Multi Lambda  
54  
55 fluorescence detector. The LC system consisted of a water binary pump, model 1525 (Milford,  
56  
57  
58  
59  
60

1  
2  
3 MA, USA), with an autosampler model 717. Waters solvent delivery system was used to operate  
4 the isocratic flow. Data acquisition was carried out using Empower software. The  
5 chromatographic separation was performed using a Nucleodur C18 Isis column (150 mm × 4.5  
6 mm, 5 μm) manufactured by Macherey-Nagel, Duren, Germany. An isocratic mobile phase  
7 consisting of 20 mM potassium dihydrogen orthophosphate buffer, pH 3.2 ± 0.05: acetonitrile  
8 (45:55, v/v) eluted at a flow rate of 1 mL/min. The buffer was adjusted to pH 3.2 ± 0.05 using  
9 50% formic acid, filtered through a Millipore membrane filter (0.22 μm) from Nihon, Millipore  
10 (Yonezawa, Japan) and degassed in an ultrasonic bath for 5 min. The injection volume was 20  
11 μL and effluent was monitored using fluorescence detection set at 280 excitation and 325 nm  
12 emission wavelength, having column oven temperature of 40°C ± 0.2°C and sample cooler  
13 temperature of 8°C ± 0.2°C.

28

29 **2.5. Sample preparation.** A simple liquid liquid extraction (LLE) method was employed to  
30 extract both analyte and IS from plasma. All samples (stored at -80 °C) were thawed before  
31 sample preparation. An aliquot of 150 μL of plasma sample, 15 μL of IS solution (20 μg/mL of  
32 telmisartan) was added into a clean glass tube and vortex-mixed for 30 sec followed by addition  
33 of 2 mL of diethyl ether into each tube. The vortex-mixing was repeated for further 2 min  
34 followed by centrifugation at 4000 g for 5 min at 4 °C. After centrifugation, the upper organic  
35 layer was transferred into a clean tube and evaporated to dryness under the gentle stream of  
36 nitrogen at 35 °C. The residue was reconstituted with 200 μL of mobile phase, out of which 20  
37 μL was injected into the HPLC for analysis.

49

50 **2.6 Method validation.** Assay validation was performed in human plasma in accordance with  
51 international guidelines for bioanalytical method validation recommended by USFDA and  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 EMEA.<sup>14,15</sup> The validation parameters included selectivity and specificity, linearity and  
4  
5 sensitivity, precision and accuracy, recovery, carry-over effects and stability.  
6  
7

8 **2.6.1. Selectivity and specificity.** Assay selectivity was evaluated in six blank plasma  
9  
10 samples which were obtained from six different lots to test for any possible endogenous  
11  
12 interference at the retention time of canagliflozin and IS. These blank plasma samples were  
13  
14 processed by the proposed extraction method and the response of co-eluting interferences was  
15  
16 evaluated by comparing their chromatograms with plasma spiked with analyte at LLOQ (16.13  
17  
18 ng/ mL) level and IS at 2 µg/ mL level.  
19  
20  
21

22 **2.6.2. Assay linearity and sensitivity.** The assay linearity was determined by preparing  
23  
24 calibration curves in human plasma in triplicate, ranging from 16.13 to 6000 ng/mL  
25  
26 concentration of the analyte. Calibration curves were obtained by plotting the peak area ratios of  
27  
28 analyte to IS (y-axis) versus the nominal concentration of analyte (x-axis) using weighted linear  
29  
30 regression. The determination coefficient ( $r^2$ ) for each calibration curve was required to be  $\geq 0.99$   
31  
32 and the linearity was evaluated by duplicate processing of calibration curve and the back  
33  
34 calculated concentrations at each point have to be within  $\pm 15\%$  deviation from the nominal  
35  
36 value. The LLOQ was defined as the lowest concentration of analyte in plasma calibration curve  
37  
38 that could be detected with an acceptable precision ( $\leq 20\%$ ) and accuracy  $\pm 20\%$ .  
39  
40  
41  
42  
43  
44

45 **2.6.3. Precision and accuracy.** Precision and accuracy was determined in human plasma at  
46  
47 four different QC concentrations (LLOQ QC, LQC, MQC and HQC). The intraday precision and  
48  
49 accuracy were determined by analyzing 6 replicates of each QCs on the same day, while the  
50  
51 inter-day precision and accuracy were determined in by analyzing 18 replicates over three  
52  
53 consecutive days. The deviation in mean value of precision was limited to  $< 20\%$  for the LLOQ  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 QC and 15 % for the other QC samples and accuracy was limited to be within  $\pm 20$  % for the  
4  
5 lowest QC samples and  $\pm 15$  % for the other QC samples.  
6  
7

8 **2.6.4. Recovery.** The extraction recovery of canagliflozin was determined at three QC  
9 levels (LQC, MQC and HQC) by comparing peak area response ratio of plasma spiked with  
10 analyte prior to extraction with those spiked with analyte after the extraction. Same procedure  
11 was followed to assess percentage extraction recovery for IS at single concentration of 2  $\mu\text{g}/\text{mL}$ .  
12  
13  
14  
15

16 **2.6.5. Carry-over effects.** For a robust and long term performance of the assay, it is  
17 important to eliminate any expected carry-over effect. The carry-over effects in respect to  
18 autosampler contamination was assessed in triplicate by injecting double blank processed plasma  
19 samples after an upper limit of quantification (ULOQ) processed sample. It was calculated by  
20 comparing the percentage peak area of double blank plasma to the area of the LLOQ sample.  
21 The same procedure was followed for IS also. The peak area response for blank plasma extract  
22 was limited to  $\leq 20\%$  of the peak area of the LLOQ and  $\leq 5\%$  of the IS to rule out any carry-over  
23 effect.  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 **2.6.6. Stability.** The stability of canagliflozin was evaluated in human plasma by analyzing  
37 six replicates of QC samples (LQC and HQC) under various storage conditions. All stability  
38 parameters were evaluated against freshly prepared plasma calibration curves. Bench-top  
39 stability of canagliflozin was determined by processing and analyzing QC samples after keeping  
40 them for 8 h at room temperature. Freeze-thaw stability was determined after storing the spiked  
41 QC samples at  $-80$  °C and thawing at  $25$  °C for three cycles. In injector stability was determined  
42 by analyzing the reconstituted QC samples in mobile phase after keeping it for 2 days in the  
43 auto-sampler at  $8$  °C. Long-term stability was determined by analyzing the spiked QC plasma  
44 samples which were stored at  $-80$  °C for 90 days. The stock solutions and working solutions of  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 canagliflozin and IS were also evaluated for their stability at room temperature for 12 h and at  
4 refrigerator temperature (4 °C) for 15 days. The peak area ratio of stock solutions and working  
5 solutions were compared to peak area ratios after injection of freshly prepared solution. The  
6 stability samples were considered stable if the deviation from the mean calculated concentration  
7 of quality control samples were found to be within the limits of accuracy ( $\pm 15\%$ ) and precision  
8 ( $\leq 15\%$ ).  
9

10  
11  
12  
13  
14  
15  
16  
17 **2.7. Incurred samples reanalysis** Since we are in academic institution and don't have a  
18 hospital or clinical pharmacology unit, and also due to ethical issues pertaining to use of drugs in  
19 human subjects, the study in patients or normal volunteers could not be taken up. However  
20 performance of this newly developed assay in real plasma sample was confirmed by reanalysis of  
21 some spared rat plasma samples of previous pharmacokinetic study of canagliflozin in rats.<sup>13</sup>  
22 Before analysis, a partial validation of this assay in term of precision and accuracy was  
23 performed in rat plasma. Approximately 30 % of rat plasma samples stored in a freezer at  $-80\text{ }^{\circ}\text{C}$   
24 for 200 days were randomly selected, thawed and processed for re-analysis.

### 39 **3. Results and discussion**

40  
41  
42 **3.1. Florescence sensitivity test and internal standard selection.** As compared to UV, FLD  
43 usually offer high selectivity and more sensitivity. Moreover the signal intensities are very low  
44 compared to UV absorption and hence can measure ideally with a very low background noise  
45 level. In this study, canagliflozin was identified as florescence sensitive as it produced maximum  
46 absorbance at 280 nm and the corresponding emission at 325 nm. For the selection of an  
47 appropriate internal standard, some florescence sensitive compounds e.g. motelukast,  
48 gemifloxacin, valsartan and telmisartan were screened, but most of them showed low response or  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 being interfered by endogenous matrix. Telmisartan was chosen as it was co-eluted with  
4  
5 canagliflozin at appropriate retention time with minimum interferences of plasma matrix and  
6  
7 high resolution under the proposed chromatographic conditions.  
8  
9

10  
11 **3.2. Optimization of the chromatographic conditions.** This HPLC-FLD assay aimed to  
12  
13 develop a reverse phase sensitive chromatographic system capable of eluting both analyte and IS  
14  
15 from plasma samples. Chromatographic separation by using different composition of mobile  
16  
17 phase at different ratios, pH of the buffer and different analytical columns were tried to achieve  
18  
19 good resolution by optimizing the chromatographic parameters like retention factor, selectivity  
20  
21 (separation factor) and efficiency. The retention factor was optimized by adjusting the strength of  
22  
23 organic modifiers in mobile phase and separation factor by optimizing the ratio of organic  
24  
25 modifiers in mobile phase, pH of mobile phase and temperature of column. Considering the all  
26  
27 above parameters, an isocratic mobile phase containing buffers e.g. disodium monohydrogen  
28  
29 phosphate, potassium dihydrogen orthophosphate, ammonium acetate) at different pH with  
30  
31 organic modifiers e.g. methanol, acetonitrile were tried. Finally, the mobile phase consisting of  
32  
33 acetonitrile and 20 mM potassium dihydrogen orthophosphate buffer adjusted to pH  $3.2 \pm 0.05$   
34  
35 using 50% formic acid showed best separation of both analyte and IS and was selected for  
36  
37 analysis. Although the retention factor was comparatively lower with the optimized  
38  
39 chromatographic condition, but high selectivity and efficiency resulted to separation of analyte  
40  
41 and IS with high resolution. Flow rate and ratio of buffer to organic phase were also optimized to  
42  
43 achieve maximum possible short runtime with enhanced analytical signal response. A number of  
44  
45 reversed-phase C<sub>18</sub> columns, such as Nucleosil, Bondapak, Nucleodur Isis and Novapak were  
46  
47 tested and compared to achieve high efficiency of chromatographic separation. Finally  
48

60

1  
2  
3 Nucleodur Isis (150 mm × 4.5 mm, 5 μm) was chosen as it produced better peak shape with high  
4 efficiency and sensitivity.  
5  
6

7  
8 **3.3. Sample preparation optimization.** Sample extraction optimization is the most critical step  
9 to improve sensitivity and recovery of assay for accurate determination of analytes in biological  
10 fluids. With the time-saving advantage and its simplicity, the protein precipitation method was  
11 tried initially using acetonitrile and methanol as protein precipitating agent. Unfortunately, the  
12 result was not satisfactory because of its high noise and interferences by endogenous plasma at  
13 the retention time of analyte and IS. Consequently, the LLE method was tried using ethyl acetate,  
14 diethyl ether, n-hexane and dichloromethane. Ethyl acetate and diethyl ether produced better  
15 results with minimum interferences at the retention time of analyte and IS. Finally diethyl ether  
16 was selected as it produced maximum recovery compared to ethyl acetate. The percentage  
17 extraction recoveries of canagliflozin and IS using diethyl ether was ≥87.7% and 77.1%,  
18 respectively (section 3.4.4), which was greater than ethyl acetate as extracting agent.  
19

### 34 **3.4. Method validation**

35  
36 **3.4.1 Selectivity and specificity.** There was no evidence of endogenous interfering peak  
37 nearby the retention times of canagliflozin and IS in all tested lots of blank plasma samples under  
38 the proposed chromatographic condition. Representative chromatograms of blank plasma and  
39 plasma spiked with IS only are shown in fig. 2 A and 2B, respectively.  
40  
41  
42  
43  
44  
45

46 **3.4.2. Linearity and lower limit of quantification.** Excellent linear relationship was  
47 observed between peak area ratios of canagliflozin and IS versus plasma concentrations over a  
48 range of 16.13-6000 ng/mL. The best linear fit with lowest total bias was achieved using  $1/X^2$   
49 weighing factor and was used to back calculation of plasma calibration curve concentrations.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
The good linearity of plasma calibration curves was evident from the mean ±SD values of

determination coefficient ( $r^2$ )  $0.994 \pm 0.002$ ; slope  $0.0012 \pm 0.00033$  and intercept  $0.1054 \pm 0.058$ . The back calculated concentrations at all point on the plasma calibration curves were within the  $\pm 15\%$  of the nominal concentrations (Table 1). Usually, LLOQ (sensitivity) is one of the limitations of HPLC assay for its application in pharmacokinetic study. This assay offered LLOQ 16.13 ng/mL in human plasma. The reported  $C_{\max}$  of canagliflozin after oral administration of its lowest recommended therapeutic dose, i.e. 50 mg, is 426 ng/mL in diabetic patient [12], i.e. 26 times higher than the LLOQ of this assay. That means this assay is adequate sensitive for the quantitation of canagliflozin in resource limited laboratory for routine pharmacokinetic study. Representative chromatograms of plasma spiked with LLOQ and MQC levels are shown in fig. 3A and 3B, respectively. Both canagliflozin and IS were eluted at 2.8 and 5.8 min, respectively with a total run time of 8 min only. The linearity in plasma was achieved up to 6000 ng/mL (ULOQ) concentration, which was 14 times greater than the  $C_{\max}$  of lowest therapeutic dose.

**3.4.3. Precision and accuracy.** The comparative results of intra- and inter-day precision and accuracy for canagliflozin at four QC levels (LLOQ QC, LQC, MQC and HQC) by HPLC-FLD in human plasma and by using UHPLC-MS/MS assay in rat plasma<sup>13</sup> are presented in table 2. In the present HPLC-FLD assay, the intra-day and inter-day precision values (expressed as % CV) were  $\leq 12.8\%$  and  $\leq 11.2\%$ , respectively. Similarly, the intra-day and inter-day accuracy ranged from 93.3-108.5% and 94.9-110.4%, respectively. The results showed that the assay met the desired level of acceptance criteria similar to previously reported UHPLC-MS/MS assay and hence was considered accurate and precise for application in determination of canagliflozin in human plasma.

60

**3.4.4. Recovery.** The % mean extraction recovery of canagliflozin using the proposed extraction method at LQC, MQC and HQC levels were found to be 92.6%, 84.8% and 87.7% with % CV of 3.9%, 7.2% and 4.7%, respectively. Similarly for IS it was 77.1% with % CV of 4.8%. This result indicates that the recovery of canagliflozin by LLE method using diethyl ether as extracting solvents was in the acceptable range, consistent and concentration independent. So the extraction process of plasma sample was sufficient to isolate the canagliflozin and IS from plasma.

**3.4.5. Carry-over effects.** No significant peaks were observed in the chromatograms of blank plasma samples, injected just after highest concentration level of calibration curve. Therefore, the carryover effects were considered to be negligible for this assay. However, a flush solvent of 80:20 v/v acetonitrile:water is recommended for the injection needle washing, after every 10-15 unknown samples.

**3.4.6. Stability.** The comparative stability results of canagliflozin under different storage conditions (freeze-thaw, autosampler, in injector, short-term and long-term) by HPLC-FLD assay in human plasma and UHPLC-MS/MS assay in rat plasma<sup>13</sup> are summarized in table 3. The results demonstrated that canagliflozin spiked plasma was stable during three cycles of freeze-thaw, 48 h in autosampler after post preparation, at least 8 h at room temperature, and up to 90 days at around  $-80^{\circ}\text{C}$  in both assay. The stock solutions and working standard of canagliflozin and IS were also found to be stable for 15 days at refrigerator temperature (below  $10^{\circ}\text{C}$ ). The deviation of mean test responses (% CV) was within  $\pm 15\%$  at LQC and HQC concentration level. Thus, there is no indication of canagliflozin instability in human plasma samples which can affect the assay performance.

1  
2  
3 **3.5. Incurred sample reanalysis.** The % difference in the concentrations of canagliflozin  
4 achieved at different time points in rats (n=6) using this HPLC assay and our previously reported  
5 UPLC-MS/MS assay was presented in table 4. The results indicate that approx. 77% of derived  
6 concentrations data for canagliflozin using both assay were a % difference of <20%. These  
7 results imply the suitability of this assay for quantitative deamination of canagliflozin in real  
8 plasma samples.  
9

### 10 **3.6. Assay performance of HPLC-FLD and UHPLC-MS/MS**

Detection in MS is based on the determination of the mass of a molecule by measuring the m/z of its protonated or deprotonated ion which produced depending upon its ionization in positive or negative mode, respectively. Although both positive and negative ions can be analyzed by MS, the majority of instruments are used to investigate positive ions because in most ion sources they are produced in larger number than negative ions. Our UHPLC-MS/MS assay was based on ESI negative mode, because in positive mode canagliflozin produced sodium and ammonium adducts ion. So the chromatographic condition was simple acetonitrile and water (80:20) to avoid adducts ions formation. However, in this HPLC-FLD assay where ionization is not an issue chromatographic condition was optimized by using different buffers with organic modifiers as mobile phase. Similarly in sample preparation procedure, previously used protein precipitation using acetonitrile produced high noise and interferences by endogenous plasma at the retention time of analyte and IS under proposed chromatographic condition. Hence, sample preparation in HPLC-FLD assay using liquid liquid extraction was preferred for the extraction of analyte and IS from plasma samples. In spite of above differences in assay performance, we have successfully developed this HPLC-FLD assay having almost similar range of plasma calibration curve (16.13-6000 ng/mL).

## 4. Conclusion

In this study, a simple sensitive and reliable HPLC-FLD assay was developed and validated for the quantification of canagliflozin in human plasma. To the best of our knowledge this is the first validated HPLC-FLD assay for the determination of canagliflozin in plasma samples. Compared to previously reported MS/MS assays, this is more simple and economical, which make it suitable for use in pharmacokinetic study in all laboratories irrespective of whether they are equipped with sophisticated instruments or not.
