## Abstract

A simple and sensitive HPLC-MS/MS method was developed for simultaneous determination of nine kinds of (D) - and (L)-amino acid enantiomers in amino acid tablets. 7-chloro-4-nitrobenzoxadiazole (NBD-Cl) was selected as derivatization reagent, and the derived amino acid enantiomers were enantioseparated on Sumichiral OA-2500S (250 mm×4.6 mm, 5 μm) column, using a mobile phase composed of acetonitrile-methanol (50:50, v/v) containing 0.5% formic acid at the flow rate of 1.0 mL·min<sup>-1</sup> with split ratio of 1:3. Sensitive detection was performed with 4000 Qtrap MS/MS system in electrospray-ionization source by negative mode. The calibration curves for the determination of all the nine pairs of amino acid enantiomers showed good linearity ( $R^2 > 0.999$ ) over the investigated ranges from 0.15 to 30 μg·ml<sup>-1</sup> for the (D)-enantiomers and from 3.14 to 620 μg·ml<sup>-1</sup> for the (L)-enantiomers, respectively. The assay was reproducible with overall intra- and inter-day variations of less than 7.7%. The detection for (D)-amino acid enantiomers was selective and sensitive, and trace amount of them could be detected and quantified, even if in the presence of massive corresponding (L)-enantiomers. The validated method was successfully applied to simultaneous quantitation of the nine kinds of (D) - and (L)-amino acid enantiomers in commercial tablets.

## 1. Introduction

Amino acids are essential for life, and have many functions in metabolism<sup>1,2</sup>. Amino acid-induced protein synthesis leads to increased muscle mass/function and physical functioning, a factor that positively affects quality of life. Several amino acids are precursors of brain neurotransmitter synthesis including serotonin, dopamine, norepinephrine, relevant for mood and behavior. In clinical practice, amino acid supplement has hepatoprotective effects<sup>3</sup>, as well as improvement in porto-systemic encephalopathy<sup>4</sup> and depressive symptoms<sup>5</sup>, etc. So, amino acid has particularly important function in our daily life.

With the exception of glycine, all encoded protein amino acids have at least one chiral center (enantiomers) or even two (epimers). (L)-Amino acids and their derivatives are significant biochemical compounds that constitute the building blocks of proteins, neurotransmitters, hormones, and nucleic acids, thus play a very important role in nutrition, medicine, and agriculture. While (D)-amino acids, which are virtually nonexistent for protein synthesis, are undesirable in food for nutritional reasons. Since superfluous (D)-amino acid may lead to overloading of the (D)-amino acid oxidase system, loss of digestibility (due to racemization), loss of essential amino acids, eventually superfluous (D)-amino acid are toxic over the long-term<sup>6</sup>. Therefore it is crucial to control the levels of (D)-amino acids in preparations in order to avoid potential toxic effects and keep the balance of D-amino acids in mammal.

However, (D)- and (L)-amino acid enantiomers have not been distinguished in commercial amino acid tablets, and (D)-amino acid enantiomers have not been focused on, either. Amino acid content assay methods using titration were provided in the United States Pharmacopoeia (potentiometric titration, the USP 34-NF 29), the British Pharmacopoeia (BP2010), Japan's Specifications and Standards for Food

1  
2  
3 Additives Monograph (JFA 7th edition), the Korea Pharmacopoeia (KP 9th edition),  
4 the Korea Food Additives Code 2011 (KFA), and the Joint FAO/WHO Expert  
5 Committee on Food Additives (JECFA). The amino acid contents were expressed as  
6 (L)-amino acids without concerning the presence of (D)-enantiomers. Therefore this  
7 resulted in poor correlation between amino acid titration data and content data of  
8 (L)-amino acid<sup>7</sup>. Analytical methods based on high performance liquid  
9 chromatography (HPLC)<sup>8, 9</sup>, capillary electrophoresis<sup>10, 11</sup>, enzymatic<sup>12</sup> and  
10 immunochemical biosensors<sup>13</sup>, etc. were reported. Comprehensive reviews on analysis  
11 of amino acid enantiomers were given<sup>14, 15</sup>. Some of these methods had disadvantages  
12 like low precision, bad repetitiveness, and difficulty in precise quantification.  
13 Recently, HPLC/mass spectrometry (MS) based methods have been developed for  
14 chiral analysis of amino acids aiming for improved method selectivity and detection  
15 sensitivity<sup>16-19</sup>. However, as far as we are aware, most of these developed methods are  
16 dealing with enantioseparation of certain amino acids or single-enantiomer content  
17 determinations, and there is still a big challenge to simultaneous determination of  
18 various amino acids enantiomers. Consequently, it is significant to establish a more  
19 accurate and sensitive method which could differentiate (D)-enantiomers from  
20 (L)-enantiomers and simultaneous determine both the two types of amino acid  
21 enantiomers.

45 Enantioseparation of amino acid enantiomers has been the focused area of our  
46 group and a method to separately determinate enantiomeric purity of a series  
47 of (L)-amino acids with pre-column derivatization and chiral stationary phase was  
48 developed by us<sup>20</sup>. On the basis of the previous study, a new method was achieved by  
49 pre-column derivatization with 7-chloro-4-nitrobenzoxadiazole and detected with  
50 4000 Qtrap mass spectrometry. This proposed method was more sensitive and

1  
2  
3 convenient owing to the merits of the derivatization and mass spectrometry detection.  
4  
5 Take D-Ala as an example, in our formerly developed HPLC method, the LOD was  
6  
7 300 ng·ml<sup>-1</sup> and LOQ was 100 ng·ml<sup>-1</sup><sup>20</sup>. And in the analysis of underivatized chiral  
8  
9 amino acids by liquid chromatography–ionspray tandem mass spectrometry using  
10  
11 chiral stationary phase, the LOD was 40 ng·ml<sup>-1</sup><sup>21</sup>. While in the proposed method, it  
12  
13 was 5 ng·ml<sup>-1</sup> and 1 ng·ml<sup>-1</sup>, respectively for LOD and LOQ. Furthermore, it enabled  
14  
15 simultaneously determination of 9 kinds of amino acid enantiomers for the first time,  
16  
17 including alanine (Ala), leucine (Leu), valine (Val), proline (Pro), phenylalanine (Phe),  
18  
19 methionine (Met), serine (Ser), threonine (Thr) and tyrosine (Tyr). All of the nine  
20  
21 investigated amino acids are primary components in commercail amino acid  
22  
23 preparations, and have important physiological activities for human<sup>22-24</sup>. Furthermore,  
24  
25 after fully validation according to the guidance of ICH, the method was successfully  
26  
27 applied to simultaneous quantitation of the nine kinds of amino acid enantiomers in  
28  
29 the tablets.

## 33 34 35 **2. Materials and methods**

### 36 37 38 **2.1. Chemical and reagents**

39  
40 Four kinds of commercial amino acid tablets were purchased from market in China.  
41  
42 (D)-, (L)-alanine (Ala), (D)-, (L)-leucine (Leu), (D)-, (L)-valine (Val), (D)-, (L)-  
43  
44 proline (Pro), (D)-, (L)-phenylalanine (Phe), (D)-, (L)-methionine (Met), (D)-,  
45  
46 (L)-serine (Ser), (D)-, (L)- threonine (Thr) and (D)-, (L)- tyrosine (Tyr) were obtained  
47  
48 from Sigma Chemical Co. (St Louis, MO, USA). 7-chloro-4-nitrobenzoxadiazole  
49  
50 (NBD-Cl) was purchased from ACROS ORGANICS (Belgium). Methanol and  
51  
52 acetonitrile of HPLC grade were provided by Fisher Chemicals (Fair Lawn, NJ, USA).  
53  
54 All the other reagents were of analytic grade. Redistilled and deionized water was  
55  
56 used throughout the study.  
57  
58  
59  
60

## 2.2 Instrumentation and chromatographic conditions

Chromatographic runs were carried out using an XR LC-20 AD Prominence™ HPLC system equipped with a binary pump, a degasser, an auto sampler, a thermostatted column compartment (Shimadzu, Japan) and a 4000 QTRAP™ MS/MS system from AB Sciex equipped with a turbo ion spray source (Foster City, CA, USA). All the operations, the acquiring and analysis of data were controlled by Analyst (version 1.6, AB Sciex, USA). Enantiomers were enantioseparated on Sumichiral OA-2500S column (250 mm×4.6 mm, 5 μm) protected by a matched Pirkle-type chiral stationary phase column pre-filter (10 mm×4 mm, 5 μm) at 40 °C. Analysis was completed with an isocratic elution of 0.5% formic acid in 50% acetonitrile (A) and 50% methanol (B). Efficient and symmetrical peaks were obtained at a flow rate of 1.0 ml·min<sup>-1</sup> with split ratio of 1:3 and a sample injection volume of 2 μL. The detection of the analytes was performed in the multiple reaction monitoring mode (MRM) using an electrospray negative ionization (ESI) under following conditions: Ion Spray Voltage 5500 V, Vacuum Gauge (10e<sup>5</sup>) 2.8 Torr and source temperature 550 °C. Nitrogen was used as gas 1, gas2 and curtain gas at a flow rate of 50, 50 and 30 psi, respectively. The quantitative parameters were shown in Table 1.

## 2.3 Preparation of standard and calibration solutions

Nine tested (D)-amino acids stock solutions (I) were prepared by dissolving accurately weighed amounts of approximately 10 mg of each compound in 10 mL of demineralized water (1.00 mg·ml<sup>-1</sup>). While nine tested (L)-amino acids stock solutions (II) were prepared in water at the concentration of 10.0 mg·ml<sup>-1</sup>. The stock solutions (III) of racemic amino acid enantiomers were prepared at a concentration of 1 mmol·L<sup>-1</sup> in water.

All the stock solutions were stored in a refrigerator (4 °C) protected from light.

1  
2  
3 The calibration standards at six levels were prepared by appropriately mixed and  
4  
5 further diluted stock standard solutions.  
6

#### 7 8 **2.4 Preparation of sample**

9  
10 A number of ten accurately weighed tablets were ground into a fine powder using a  
11  
12 glass mortar and pestle. A quantity of the powder was transferred to 10 mL volumetric  
13  
14 flasks. Then, 5 mL of demineralized water was added. After standing for 30 min under  
15  
16 ultra-sonication at ambient temperature, the flask was adjusted to volume and mixed  
17  
18 well. The resulting solution was filtered using 0.22  $\mu\text{m}$  filter membrane. The filtered  
19  
20 solution was transferred into another clean tube and submitted to NBD-Cl  
21  
22 derivatization procedure.  
23

#### 24 25 **2.5 Derivatization procedure**

26  
27 The 100  $\mu\text{L}$  sample solution was alkalized by adding borate buffer solution (100  
28  
29  $\text{mmol}\cdot\text{L}^{-1}$  at pH 9.0), followed by 100  $\mu\text{L}$  NBD-Cl ( $16 \text{ mmol}\cdot\text{L}^{-1}$ ) diluted with  
30  
31 methanol. The mixture was vortexed and heated at 60  $^{\circ}\text{C}$  in the water bath for 1 h  
32  
33 protected from light, followed by cooling at 4  $^{\circ}\text{C}$  in refrigerator. After heating, the  
34  
35 mixture was evaporated to dryness under nitrogen. The residue was reconstituted in  
36  
37 0.1 mL mobile phase, vortex-mixed for 3 min, then sonicated for 3 min followed by  
38  
39 being centrifuged at 12 000 rpm for 5 min. Finally, the 2  $\mu\text{L}$  supernatant was injected  
40  
41 for HPLC-MS/MS analysis. For blank sample, 100  $\mu\text{L}$  water was used instead of  
42  
43 sample solution.  
44  
45

#### 46 47 **2.6 Method validation**

48  
49 The method was fully validated according to ICH guidelines for validation of  
50  
51 analytical procedures.  
52

##### 53 54 **2.6.1 Linearity, limits of detection (LOD) and quantitation (LOQ)**

55  
56 Appropriate amounts of amino acid stock solutions (I) were diluted with water to give  
57  
58  
59  
60

1  
2  
3 six concentrations covered from 0.5 to 10  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Ala, 1.5 to 30  $\mu\text{g}\cdot\text{mL}^{-1}$  for  
4  
5 D-Leu, 0.25 to 5  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Val, 0.6 to 12  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Pro, 1.5 to 30  $\mu\text{g}\cdot\text{mL}^{-1}$   
6  
7 for D-Phe, 0.6 to 12  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Met, 0.19 to 3.8  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Ser, 0.15 to 3  
8  
9  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Thr, 1.5 to 30  $\mu\text{g}\cdot\text{mL}^{-1}$  for D-Tyr, and 7.2 to 144  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Ala,  
10  
11 12.4 to 248  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Leu, 10.0 to 200  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Val, 31 to 620  $\mu\text{g}\cdot\text{mL}^{-1}$  for  
12  
13 L-Pro, 14.7 to 294  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Phe, 3.26 to 6.52  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Met, 3.14 to 62.8  
14  
15  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Ser, 4.5 to 90  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Thr, 13.2 to 264  $\mu\text{g}\cdot\text{mL}^{-1}$  for L-Tyr,  
16  
17 respectively. Linearity was evaluated by linear least-squares regression analysis.  
18  
19 Limits of quantification (LOQ) were calculated the lowest concentration producing  
20  
21 signal-to-noise ratio of at least 10:1. Limits of detection (LOD) were calculated as the  
22  
23 lowest concentration producing signal-to-noise ratio of at least 3:1  
24  
25  
26

### 27 **2.6.2 Accuracy**

28  
29 The accuracy of the method described for the determination of amino acid  
30  
31 enantiomers in tablets were calculated as the percent recoveries. And the recovery  
32  
33 studies were carried out by adding known quantities of standards at three different  
34  
35 levels to the pre-analyzed sample, 80%, 100% and 120% of the amino acids  
36  
37 concentration level of the tablets. Three replicates were prepared for each  
38  
39 concentration level. Measured values were compared with the theoretical  
40  
41 concentration. Recovery for pharmaceutical formulations should be within the range  
42  
43 100  $\pm$  10%. The relative standard deviations (R.S.D.) values of individual  
44  
45 measurements were also determined.  
46  
47  
48

### 49 **2.6.3 Precision**

50  
51 The precision of the proposed method was determined by repeatability (intra-day) and  
52  
53 intermediate precision (inter-day). The intermediate precision was studied by  
54  
55 comparing the assays on different days (3 days). Six sample solutions were prepared  
56  
57  
58  
59  
60

1  
2  
3 and assayed daily.  
4

#### 5 **2.6.4 Stability**

6  
7 The stability of amino acid enantiomers in sample solutions was tested using the  
8 sample solutions at the six different time of duration at stored temperature (4 °C)  
9 protected from light. The samples were examined at 0, 2, 4, 8 and 12 h after  
10 derivatization. The R.S.D. of injection sample solutions at different time was paid  
11 close attention to.  
12  
13  
14  
15  
16  
17

#### 18 **2.6.5 Specificity**

19  
20 The specificity was evaluated by comparing chromatograms of blank sample added  
21 water instead of sample solutions, the amino acid standard solutions and the amino  
22 acid tablet solutions. All the chromatograms were examined to demonstrate the  
23 absence of interference with the auxiliary material of amino acid tablets and the  
24 derivatization reagents. And the retention times of analytes and IS in standard  
25 solutions should be equal to those in samples.  
26  
27  
28  
29  
30  
31  
32  
33

### 34 **3. Results and discussion**

#### 35 **3.1 Optimization of derivatization conditions**

36  
37 A standard solution (III) of nine kinds of (D) - and (L)-amino acid enantiomers (1  
38 mmol·L<sup>-1</sup>) were used to investigate the optimum derivatization conditions. The  
39 derivatization reaction of amino acid and NBD-Cl proceeded under alkaline  
40 conditions. During the process of reaction, amino acid reacted with NBD-Cl to give a  
41 kind of derivatives compound, i.e. amino acid-NBD. The reaction diagram for amino  
42 acid derivatization of amino acid with NBD-Cl was shown in Fig. 1.  
43  
44  
45  
46  
47  
48  
49  
50  
51

52  
53 The effects of concentrations of derivatization reagent, pH values, derivatization  
54 temperatures and time on derivative intensity have been paid close attention to. To  
55 optimize the derivatization conditions, a single-factor test was performed. Since  
56  
57  
58  
59  
60

1  
2  
3 different ratios of NBD-Cl to amino acid could influence the degree of derivatization,  
4  
5 different concentrations of derivatization reagent from 1 mmol·L<sup>-1</sup> to 5 mmol·L<sup>-1</sup> were  
6  
7 studied whereas the concentration of amino acid was fixed at 1 mmol·L<sup>-1</sup>. The result  
8  
9 was shown in Fig. 2A. The derivatization reagent, four times of amino acid  
10  
11 concentration, was used in the recommended procedure which provided almost  
12  
13 maximum and constant peak areas as for all the nine kinds of amino acids.  
14  
15

16  
17 Different pH values could also affect derivative intensity and it was a critical  
18  
19 factor for the derivatization reaction. Thus the pH values ranging from 7.5 to 10.0  
20  
21 were performed to find the best derivative pH value. As shown in Fig. 2 B, it was  
22  
23 found that peak areas of the derivatives reached plateau at pH 8.5. As a result, the  
24  
25 optimum pH value of borate buffer solution of 8.5 was selected.  
26

27  
28 The effects of derivatization temperatures (40, 50, 60 and 70 °C) and reaction  
29  
30 time (50, 60, 70, 80 and 90 min) on derivatization yields were investigated, and the  
31  
32 results were displayed in Fig. 2C and Fig. 2D, respectively. The time effect studies  
33  
34 were carried out to a maximum of 90 min. The maximum and constant peak areas  
35  
36 were obtained after reacting for 60 min, and there were no significant changes in peak  
37  
38 areas with increasing time. Hence, the appropriate reaction time was decided to be 60  
39  
40 min. As for the derivatization temperature, it was examined from 40 to 90 °C. Adduct  
41  
42 yields increased indistinctively before derivatization temperatures >70 °C and it  
43  
44 decreased after derivatization temperatures >70 °C. This may be due to the  
45  
46 decomposition of the adducts. Therefore, 70 °C was taken as the optimal  
47  
48 derivatization temperature for the derivatization process.  
49  
50

### 51 52 **3.2 Optimization of chromatographic and mass conditions**

53  
54 Under the electrospray ionization conditions, a greater sensitivity was achieved for  
55  
56 nine kinds of amino acid enantiomers in the negative mode (ESI) than in the positive  
57  
58  
59  
60

1  
2  
3 mode (ESI<sup>+</sup>). The optimal conditions for the triple-quad analyzer were determined by  
4 direct infusion of the standard solutions into the mass spectrometer. Some parameters  
5 such as gas1, gas2, curtain gas, IS voltage, DP, CE and CXP were optimized in  
6 automatic runs under evaluation of the ionic sensitivity. The other parameters were  
7 adopted for the recommended value of the instrument.  
8  
9

10  
11 To optimize the peak shapes and retention times of nine kinds of amino acid  
12 enantiomers and IS, the varying proportions of methanol–acetonitrile system were  
13 investigated. The best results in terms of enantioresolution and retention of the  
14 enantiomers were obtained with the 50% acetonitrile composition (acetonitrile  
15 -methanol, v/v), whereas continuing increase of acetonitrile more than 50% resulted in  
16 a small decrease of the enantioresolution. The addition of a small amount of formic  
17 acid to the mobile phase was proved to improve peak symmetry and shape of amino  
18 acid enantiomers. For this reason, different proportions of formic acid (0.05%, 0.1%,  
19 0.3% and 0.5%) were added into acetonitrile-methanol system to investigate the effect.  
20 With the increase of the amount of formic acid, the run time was gradually shortened,  
21 but the enantioresolution would be decreased. Finally, a mobile phase composed of  
22 acetonitrile-methanol (50:50, v/v) containing 0.5% formic acid was selected for  
23 sufficient ionization response, good peak symmetry and proper retention time for the  
24 analytes and IS.  
25

44

### 45 **3.3. Method validation**

46 This method was estimated to give evidence of its applicability for its intended  
47 purpose with adequate validation characteristics.  
48  
49

#### 50 **3.3.1 Linearity, limits of detection (LOD) and quantitation (LOQ)**

51 Calibration curves for nine kinds of amino acid enantiomers were constructed by  
52 plotting concentration versus the ratio of peak area normalizations of different amino  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 acid and IS and showed good linearity in the different ranges, respectively. Linear  
4  
5 regression analysis of the curves was tabulated in Table 2. High coefficients of  
6  
7 correlation were obtained and the intercepts of the curves were not notably different  
8  
9 from zero. In spite of significant differences of the linearity ranges between (D) - and  
10  
11 (L)-amino acid enantiomers, the proposed method could still be generally suitable for  
12  
13 simultaneous determination of (D) - and (L) - amino acids enantiomers.  
14  
15

16  
17 Certain analytical parameters such as LOD and LOQ values were calculated by  
18  
19 computing the processed of integrated peak from HPLC–MS/MS, and the results were  
20  
21 also listed in Table 2. It could be found, the lowest points on the calibration curves of  
22  
23 (D)-amino acid enantiomers were in accordance with the levels of the LOQ, whereas  
24  
25 for the (L)-amino acid enantiomers, the lowest points on calibration curves were  
26  
27 significantly higher than the LOQs. This can be attributed to the fact that there were  
28  
29 large amounts of (L)-amino acid enantiomers and small amounts of (D)-amino acid  
30  
31 enantiomers in the amino acid tablets, and the ranges of calibration curves should be  
32  
33 suitable to the concentrations of practical products. If necessary, the scope of the  
34  
35 calibration curves of (L)-amino acid enantiomers could also be expanded in further  
36  
37 research.  
38  
39

### 40 41 **3.3.2 Accuracy**

42  
43 The accuracy of the method was evaluated by the mean recovery obtained from three  
44  
45 levels. At each level of amino acid concentration three determinations were performed.  
46  
47 The mean recoveries were presented in Table 3 to prove the developed method could  
48  
49 be considered accurate over the range investigated.  
50  
51

### 52 53 **3.3.3 Precision**

54  
55 To validate the precision of the proposed method, both the repeatability and  
56  
57 intermediate precision were investigated, and were expressed as R.S.D of a set of  
58  
59  
60

1  
2  
3 results. Results were presented in Table 4, which indicated good repeatability and low  
4  
5 inter- day variability with R.S.D maximum of 7.7%  
6

#### 7 8 **3.3.4 Stability**

9  
10 The R.S.D values of one derivative sample at 0, 2, 4, 8 and 12 h within a single day  
11  
12 was less than 9.1%, which proved that the derivative sample was stable over a 12 h  
13  
14 period.

#### 15 16 **3.3.5 Specificity**

17  
18 No significant interference was observed at the retention time of the nine kinds of  
19  
20 amino acid enantiomers and IS. With the help of HPLC system, high selectivity of  
21  
22 MRM mode and appropriate mobile phase, a total analysis time of less than 34 min  
23  
24 was achieved which could put high-throughput analysis for nine pairs of enantiomers  
25  
26 to practice. Typical MRM chromatograms of blank sample, amino acid standard  
27  
28 solution and amino acid tablet sample solution were shown in Fig. 3. It can be seen  
29  
30 there was no interference at the migration times of the enantiomers between standard  
31  
32 solutions sample and tablet samples, and all the nine pairs of enantiomers were  
33  
34 enantioseparated very well.  
35  
36

#### 37 38 **3.4 Method Application**

39  
40 The developed method was successfully applied to simultaneously determine the nine  
41  
42 kinds of (D) - and (L)-amino acid enantiomers in tablets. The results obtained for the  
43  
44 nine kinds of (D) - and (L)-amino acid enantiomers were given in Table 5. In the four  
45  
46 kinds of commercial amino acid tablets, both (D) - and (L) - enantiomers of all the  
47  
48 nine kinds of amino acids were detected in the amino acid tablets. Among them the  
49  
50 (L)-enantiomers were the main existent form, while the amounts of (D)-enantiomers  
51  
52 were little and varied differently according to the kinds of amino acid and brands of  
53  
54 the commercial tablets. Furthermore, this more accurate and sensitive  
55  
56  
57  
58  
59  
60

1  
2  
3 enantioseparation method for simultaneously determination of (D)-and (L)-amino acid  
4  
5 enantiomers could provide the scientific basis for the detection of amino acid  
6  
7 enantiomers in vivo and the clinical tests. The application in vivo is currently  
8  
9 underway in our group.  
10

#### 11 **4. Conclusion**

12  
13  
14  
15 In this paper, a new HPLC-MS/MS method for the simultaneous assay of nine kinds  
16  
17 of (D) - and (L) amino acid enantiomers in tablets was reported. This method was  
18  
19 simple, reliable, linear, accurate, and sensitive as well as cost-effective for quantitative  
20  
21 analysis of amino acid enantiomers in tablet. In the measured commercial amino acid  
22  
23 tablets, (L)-amino acid was the main existence, whereas there was also little  
24  
25 corresponding (D)-amino acids present. The developed method can be easily and  
26  
27 conveniently adopted for a routine analysis of (D) - and (L)-amino acids in tablets. In  
28  
29 addition, the method could be applied in vivo and the clinical tests in the long run.  
30  
31

Table 5. Content of 9 kinds of (D) - and (L)-amino acid enantiomers obtained for a commercially available Sample ( $\text{mg}\cdot\text{g}^{-1}$ )

Analyte	Brand A	Brand B	Brand C	Brand D
D-Ala	0.07	0.10	0.10	0.18
D-Leu	0.18	0.26	0.15	0.47
D-Val	0.05	0.07	0.06	0.09
D-Pro	0.20	0.59	0.34	0.43
D-Phe	0.25	0.38	0.13	0.77
D-Met	0.03	0.04	0.02	0.06
D-Ser	0.04	0.07	0.08	0.14
D-Thr	0.01	0.03	0.00	0.05
D-Tyr	0.21	0.32	0.19	0.76
L-Ala	1.13	1.30	0.87	1.73
L-Leu	4.04	4.76	1.70	6.12
L-Val	2.46	2.78	1.15	3.47
L-Pro	3.24	3.62	1.48	4.56
L-Phe	5.20	6.27	1.80	7.57
L-Met	0.96	1.17	0.42	1.53
L-Ser	1.28	1.45	0.98	1.78
L-Thr	1.18	1.33	2.09	1.74
L-Tyr	4.75	5.89	0.76	8.34
