Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

18  
19 8 **ABSTRACT**

20  
21 9 A new model of fast and convenient liquid-liquid-liquid microextraction (LLLME), combining  
22  
23 10 low-density solvent-based solvent-demulsification dispersive liquid-liquid microextraction  
24  
25 11 (LDS-SD-DLLME) and single drop microextraction (SDME), was introduced to separate sulfonamides  
26  
27 12 from environmental water samples for the first time. The extraction procedure includes a 2-min  
28  
29 13 LDS-SD-DLLME fore extraction and a 15-min SDME back-extraction. A mixture of extraction solvent  
30  
31 14 (1-octanol) and disperser solvent (methanol) was rapidly injected into the aqueous sample to form an  
32  
33 15 emulsion for pre-extraction. Then a demulsifier solvent (acetonitrile) was injected into the extraction  
34  
35 16 system. The emulsion turned clear in a few seconds and a layer of the organic phase formed at the top of  
36  
37 17 the aqueous phase. At last a drop of acceptor solution was introduced into the upper layer and the  
38  
39 18 SDME was carried out for the back-extraction. The whole procedure does not need any electric  
40  
41 19 equipment (centrifuge, stirrer or ultrasonic cleaner) because the centrifugation in DLLME and the  
42  
43 20 stirring step typically involved in SDME and LLLME are avoided by the successfully coupling of  
44  
45 21 LDS-SD-DLLME and SDME. Four sulfonamides were firstly transferred from the donor phase to the  
46  
47 22 organic phase by the LDS-SD-DLLME pre-extraction and then back-extracted into the acceptor droplet  
48  
49 23 directly suspended in the upper layer of the organic phase. Factors affecting extraction efficiency were  
50  
51 24 studied, including the organic solvent, the disperser solvent, the demulsifier solvent, the composition the  
52  
53 25 of donor phase and acceptor phase, and the extraction time. At optimal conditions, the method showed  
54  
55 26 low detection limit (0.22-1.92 µg/L) for the four sulfonamides, good linearity (from 1.0-500 to 10-500  
56  
57 27 µg/L, depending on the analytes) and repeatability (RSD below 4.6 %, n = 3). The simple, fast, and  
58  
59 28 efficient feature of the proposed method was demonstrated by the analysis of sulfonamides in the lake  
60

## 12 33 INTRODUCTION

14 34 Sulfonamides (SAs) are commonly used in aquaculture and animal husbandry owing to their  
15 35 broad-spectrum activity and efficacy as growth promoters<sup>1-2</sup>. Ultimately, the residues of SAs can be  
16 36 excreted into the environmental soil and water<sup>3-4</sup>. Some of SAs can promote the development of  
17 37 antibiotic-resistant bacteria, cause allergic reactions in human, and even possess carcinogenic potential  
18 38<sup>5-6</sup>. The content of SAs in untreated wastewaters ranges from 0.01 to 19.2 mg L<sup>-1</sup>, and in treated  
19 39 wastewaters ranges from 0.004 to 6.0 mg L<sup>-1</sup>, from a review of published data<sup>7</sup>. The European Union  
20 40 and US Food and Drug Administration (FDA) have provided that the total residues of SAs should not  
21 41 exceed 100 µg kg<sup>-1</sup> in foodstuffs, such as fish, meat, eggs, milk and dairy products<sup>8-9</sup>. Therefore,  
22 42 there is a great need to monitor the trace of these compounds in environmental water.

23 43 In general, quantitative analysis of SAs are based on chromatographic techniques such as gas  
24 44 chromatography (GC)<sup>10-12</sup>, capillary electrophoresis (CE)<sup>13-15</sup>, and high performance liquid  
25 45 chromatography (HPLC) with ultraviolet (UV)<sup>16-21</sup>, fluorescence detection (FLD)<sup>22-27</sup>, and MS<sup>28-31</sup>. In  
26 46 the past 5 years, HPLC-MS(/MS) has become the most employed analytical technique for the  
27 47 determination of SAs due to its higher selectivity and sensitivity than other instrumental methods<sup>7</sup>.  
28 48 Nevertheless, HPLC-UV presents a cheap and effective method for the determination of SAs in many  
29 49 cases<sup>16-21</sup>.

30 50 Prior to HPLC analysis, a relatively simple and effective preconcentration and clean-up  
31 51 pretreatment process is necessary to extract traces of SAs from the aqueous medium. Dispersive  
32 52 liquid-liquid microextraction (DLLME), as demonstrated advantages including rapidity, simplicity of  
33 53 operation, low cost, high recovery and enrichment factor<sup>32</sup>, has been proposed to extract sulfonamides  
34 54 from water samples<sup>8, 21, 25, 33</sup>.

35 55 Given that sulfonamide compounds are amphoteric and readily soluble in water, the  
36 56 liquid-liquid-liquid microextraction (LLLME) has been recommended for the preconcentration of  
37 57  
38 58  
39 59  
40 60

1  
2  
3  
4 57 sulfonamides from water sample either using ionic liquid<sup>34</sup> or nitroxyene<sup>1</sup> as the organic phase. In this  
5  
6 58 technique, pH adjustment in the donor phase can be used to control the hydrophilic-hydrophobic  
7  
8 59 character of sulfonamides that provides good extractability for SAs. The organic phase may also play an  
9  
10 60 efficient barrier to some interfering compounds coexisting in the aqueous phase. So the clean-up would  
11  
12 61 be improved in this way. However, the conventional LLLME is usually a time-consuming technique. It  
13  
14 62 was often observed that more time is needed to reach a good enrichment of the analytes of interest<sup>1</sup>.

15  
16 63 In response to this concern, we have developed a new format of LLLME by combining the  
17  
18 64 low-density solvent-based DLLME with single-drop microextraction (SDME) for the fast and effective  
19  
20 65 preconcentration of chlorophenols from environmental water samples<sup>35</sup>. The low-density solvent-based  
21  
22 66 solvent-demulsification DLLME (LDS-SD-DLLME), being introduced in our previous work<sup>36</sup>, has  
23  
24 67 been well evaluated for the determination of carbamate pesticides<sup>36</sup> organochlorine pesticides<sup>37</sup> and  
25  
26 68 polycyclic aromatic hydrocarbons (PAHs)<sup>38, 39</sup>. On the other hand, SDME is well known as a  
27  
28 69 simple-operation liquid-phase microextraction (LPME)<sup>40</sup>, although the instability of the suspending  
29  
30 70 droplet often limits its application to various samples. The new DLLME-SDME combination<sup>35</sup> includes  
31  
32 71 a 2-min DLLME pre-extraction and a 10-min SDME back-extraction. The acceptor droplet is directly  
33  
34 72 introduced into the upper layer of low-density organic phase after the DLLME step. The high speed and  
35  
36 73 efficiency of DLLME make the typical stirring step in SDME and LLLME unnecessary and the total  
37  
38 74 extraction time noticeably short.

39  
40 75 Here, low-density solvent-based solvent-demulsification DLLME combined with SDME was for  
41  
42 76 the first time developed in a new format for the fast three-phase microextraction of trace sulfonamides  
43  
44 77 in aqueous solution. In the proposed procedure, measured light organic solvent (1-octanol) and  
45  
46 78 methanol (disperser) were rapidly injected into the aqueous sample (donor phase) and a cloudy solution  
47  
48 79 was formed. After a 2-min pre-extraction, instead of mechanical centrifugation<sup>35</sup>, a volume of  
49  
50 80 demulsifier (acetonitrile) was employed to break down the emulsion. It cleared quickly to two layers in  
51  
52 81 a few seconds after the injection of the demulsifier. Then a droplet of acceptor phase was introduced  
53  
54 82 into the upper layer of the organic phase for the SDME back-extraction. The extreme simplicity, high  
55  
56 83 speed and efficiency of the LDS-SD-DLLME-SDME coupling make the typical centrifugation in  
57  
58 84 DLLME and stirring steps in SDME and LLLME unnecessary. Thereby simplifying the operation and

1  
2  
3  
4 85 speeding up the pretreatment of samples. The developed method was applied to analyze several  
5  
6 86 environmental water samples.  
7

## 8 **EXPERIMENTAL**

### 9 **Chemicals and supplies**

10  
11  
12 89 Sulfathiazole (STZ), Sulfamethoxazole (SMX) and Sulfamethazine (SMZ) with purity of 99.0%  
13  
14 90 were purchased from Sigma-Aldrich (Shanghai, China). Sulfanilamide (SN) with purity of 99.8% was  
15  
16 91 supplied by Sinopharm (Shanghai, China). Structure, logD values and pKa values of target  
17  
18 92 sulfonamides were shown in Table 1. Stock standard solutions of each analyte were prepared in  
19  
20 93 methanol and stored at 4 °C. Mixtures of standard working solutions for extraction were prepared daily  
21  
22 94 by diluting the stock standard solution with ultrapure water to the required concentrations.  
23

24 95 Toluene, 1-octanol, decanol, n-hexane, cyclohexane, acetone, acetonitrile and methanol were  
25  
26 96 purchased from Sinopharm (Shanghai, China). All reagents were of analytical grade or better. Ultrapure  
27  
28 97 water was produced on a Milli-Q Academic water purification system (18.2 MΩ·cm, Millipore, USA).

29  
30 98 Structure, logD values and pKa values of target sulfonamides, Sulfanilamide (SN), Sulfathiazole  
31  
32 99 (STZ), Sulfamethazine (SMZ) and Sulfamethoxazole (SMX), were shown in Table 1.  
33

34 100 The flat-cut needle tip of 10 μL microsyringe (Gaoge, Shanghai, China) was used for suspending  
35  
36 101 the single drop of the acceptor phase. Disposable Teflon sleeve (0.7 mm i.d., 1.6 mm o.d.) was  
37  
38 102 purchased from Agilent. The Teflon sleeve was cut into about 3 mm segments and replaced every new  
39  
40 103 extraction. Before use, the sleeve was cleaned with acetone, methanol and water at least 10 times,  
41  
42 104 respectively.  
43

### 44 **Instrumentation**

45  
46 106 Chromatographic analysis was performed with an Agilent 1200 HPLC system (Agilent, USA)  
47  
48 107 including a ultraviolet-visible detector (VWD), a quaternary pump, a degasser and an analytical  
49  
50 108 ChemStation. A Synergi Hydro-RP 80A C<sub>18</sub> column (250 mm × 4.6 mm, 4 μm, Phenomenex, USA) was  
51  
52 109 used for separation. The mobile phase used for separations was a binary solvent of acetonitrile : water  
53  
54 110 (1% acetic acid). Gradient elution with a flow-rate of 1.0 mL min<sup>-1</sup> was applied: initial 20% acetonitrile  
55  
56 111 a linear ramp to 35% in 4 min, held at 35%. The detection wavelength was set at 265 nm and the  
57  
58 112 analysis was carried out at 25 °C. The injection volume was 3 μL.  
59  
60

### 113 **DLLME-SDME extraction procedure**

114 The schematic procedure of LDS-SD-DLLME-SDME is shown in Figure 1. A volume of 7 mL  
115 aqueous sample (pH 4.5 adjusted by 0.05 mol/L NaH<sub>2</sub>PO<sub>4</sub>) containing analytes and 2 mol/L Na<sub>2</sub>SO<sub>4</sub> was  
116 placed in a disposable polyethylene pipette (bottom: 55 mm height and 15 mm i.d.; top: 45 mm height  
117 and 7.5 mm i.d.)<sup>35</sup>. A mixture of 200 μL 1-octanol (as extraction solvent) and 750 μL methanol (as  
118 disperser solvent) was injected rapidly into the aqueous sample through a syringe. An emulsion of the  
119 extraction solvent, disperser solvent, and aqueous sample was formed in the pipette. After a 2-min  
120 pre-extraction, an aliquot of 600 μL acetonitrile serving as the demulsifier was injected into the pipette  
121 to break down the emulsion. The mixture cleared and turned to two layers within a few seconds.

122 The acceptor solution (0.1 mol/L NaOH) was taken by means of a 10 μL microsyringe fitted with  
123 Teflon sleeve. The microsyringe was lowered down vertically and slowly until the tip of the needle was  
124 barely immersed in the upper layer of the organic phase at the narrow stem of the pipette. The acceptor  
125 solution was pushed forward to the end of the microsyringe needle and a 3 μL droplet was suspended at  
126 its tip. After a 15-min back-extraction, the acceptor droplet was retracted into the microsyringe and  
127 manually introduced to HPLC system for further analysis.

### 128 **Water samples and analytes**

129 Water samples were collected from the South Lake and a fish pond, and a site of aquaculture  
130 drainage near the campus (HZAU, Wuhan, China). The samples were filtered through the 0.45 μm pore  
131 size membrane filters into glass bottles and stored in the dark at 4 °C until their analysis (within 72 h).

## 132 **RESULTS AND DISCUSSION**

### 133 **Design of phase separation in DLLME**

134 Typically, most DLLME procedures have a centrifugation step, which is somewhat  
135 time-consuming and needs a cooling setup in cases to ensure a good phase separation. Recently in our  
136 previous work, a solvent-termination (demulsification) step was validated to be an alternative design of  
137 phase separation in DLLME<sup>36</sup>. The performance of solvent-demulsification (1 mL acetonitrile as  
138 demulsifier) was compared with the centrifugation (at 3000 r min<sup>-1</sup> for 2 min) for the separation of the  
139 dispersed organic phase and the aqueous phase. As demonstrated in Figure 2, peak areas for tested  
140 sulfonamides were higher when solvent-demulsification was used for phase separation than

1  
2  
3  
4 141 centrifugation. Solvent-demulsification rather than centrifugation was selected for the phase separation  
5  
6 142 in following experiments.  
7

#### 8 143 **Extraction solvent and its volume**

9  
10 144 The selection of organic solvent was based on the following conditions: low water solubility,  
11  
12 145 moderate solubility of target compounds in it, and having a lower density than water. Four low-density  
13  
14 146 organic solvents with different polarity, namely toluene, iso-octanol, decanol and 1-octanol were  
15  
16 147 examined for the extraction solvent. A series of experiments were performed to evaluate the extraction  
17  
18 148 solvents using 500  $\mu\text{L}$  methanol as dispersive solvent and 1000  $\mu\text{L}$  acetonitrile as demulsifier solvent. In  
19  
20 149 order to achieve equal final volume in the upper layer for different extraction solvents after DLLME,  
21  
22 150 different initial volumes of organic solvents were served based on their solubility in the extraction  
23  
24 151 system. As illustrated in Figure 3, the highest extraction efficiency was achieved with 1-octanol for most  
25  
26 152 sulfonamides. Therefore 1-octanol was selected as the organic phase.

27  
28 153 The volume of the extraction solvent is an important parameter in DLLME which may influence  
29  
30 154 the microextraction and the enrichment of the analyte. The volume of about 10-50  $\mu\text{L}$  for the extraction  
31  
32 155 solvent was usually used in conventional DLLME, whereas here the volume of 1-octanol should be  
33  
34 156 large enough to facilitate implementing the SDME back-extraction in the upper layer. Previous  
35  
36 157 experiments<sup>34</sup> showed that the final volume of the organic layer should not be less than 200  $\mu\text{L}$  in the  
37  
38 158 extraction pipette. Otherwise the upper layer would be too thin to suspend an acceptor droplet in it. In  
39  
40 159 this respect, the 1-octanol volume of 200  $\mu\text{L}$  was adopted in the following experiments.

#### 41 160 **Donor pH and addition of salt**

42  
43 161 Since sulfonamides are ordinary ampholytes, the pH of the donor phase was adjusted to  $\text{pK}_a^{\text{average}}$   
44  
45 162 to make their neutral forms dominant in the aqueous phase<sup>1</sup>. As trial results indicated, the  $\text{pK}_a^{\text{average}}$  of  
46  
47 163 sulfonamides, *i.e.* the average of  $\text{pK}_{a1}$  and  $\text{pK}_{a2}$  of the compounds, are in the range of 3.6 to 6.0 (Table  
48  
49 164 1). Accordingly, a 0.05 mol/L concentration of  $\text{NaH}_2\text{PO}_4$  was contained in the sample solution to keep  
50  
51 165 the pH value of the donor phase at 4.5.

52  
53 166 The salting-out effect is often used to increase the partition coefficient of the polar analytes to the  
54  
55 167 organic phase in liquid-liquid extraction. In the same time, salting-out phenomenon would also reduce  
56  
57 168 the solubility of the organic solvent in the donor phase, accelerating the phase separation of the organic  
58  
59  
60

1  
2  
3  
4 169 phase and the bulk sample after extraction. To this purpose, 1 mol/L of Na<sub>2</sub>SO<sub>4</sub> (or NaH<sub>2</sub>PO<sub>4</sub>) was  
5  
6 170 added in the sample solution, respectively, to investigate the salting-out effect on the extraction  
7  
8 171 efficiency. As can be seen from Figure 4-A, higher extraction efficiency was obtained when Na<sub>2</sub>SO<sub>4</sub> was  
9  
10 172 added.

11  
12 173 The solubility of Na<sub>2</sub>SO<sub>4</sub> in water varies with temperature and 2 mol/L Na<sub>2</sub>SO<sub>4</sub> is almost saturated  
13  
14 174 in the water samples at room temperature. Then the salt addition experiment was further investigated  
15  
16 175 with 0.5-2 mol/L of Na<sub>2</sub>SO<sub>4</sub> adding to the aqueous sample. The obtained results (Figure 4-B) showed  
17  
18 176 that the extraction efficiency of sulfonamides steadily increased with the content of Na<sub>2</sub>SO<sub>4</sub> increasing.  
19  
20 177 So 2 mol/L Na<sub>2</sub>SO<sub>4</sub> was added into the sample solution.

#### 21 178 **Disperser solvent and its volume**

22  
23  
24 179 The disperser solvent should be miscible between an organic phase and donor phase. Acetonitrile,  
25  
26 180 acetone and methanol were often suggested being applied as disperser in DLLME. Both acetonitrile and  
27  
28 181 acetone worked well as disperser with a low content of salt in the sample solution. Nevertheless, when 2  
29  
30 182 mol L<sup>-1</sup> Na<sub>2</sub>SO<sub>4</sub> was added into the aqueous sample, neither acetonitrile or acetone could lead to a good  
31  
32 183 emulsion of extraction solvent and the donor phase. Sometimes the clouding solution could not even be  
33  
34 184 observed. This phenomenon was explained by a remarkable intensification of the ionic strength of the  
35  
36 185 aqueous phase by adding high content of salt into it.

37  
38 186 Similar observation to the previous experiment<sup>36</sup> was obtained that methanol performed much  
39  
40 187 better than acetonitrile and acetone as the disperser solvent. A series of volumes of methanol ranging in  
41  
42 188 250-1250 μL were investigated. The experimental results showed that 750 μL methanol is a suitable  
43  
44 189 choice to ensure a good dispersion.

#### 45 190 **Demulsifier solvent and its volume**

46  
47 191 In the low-density solvent-based solvent-demulsification DLLME procedure, the water-miscible  
48  
49 192 organic solvent methanol, acetonitrile and acetone would also be used as chemical demulsifiers to break  
50  
51 193 down the dispersed system<sup>36</sup>. So the three commonly used solvents were evaluated in this work.  
52  
53 194 However, contrast to the above observation of them acting as disperser, both acetonitrile and acetone  
54  
55 195 performed better than methanol in this section as showed in Figure 5-A. The reason may be attributed to  
56  
57 196 their characteristics of low surface tension and high surface activity. Acetonitrile was chosen as the  
58  
59  
60

1  
2  
3  
4 197 demulsifier solvent in following experiments.

5  
6 198 Furthermore, the effect of the volume of acetonitrile as demulsifier solvent on the extraction of  
7  
8 199 analytes was studied. Figure 5-B shows that higher extraction efficiency was obtained by using a larger  
9  
10 200 amount of acetonitrile. On the other hand, excessive dosage of acetonitrile will cause more instability  
11  
12 201 for the acceptor droplet suspended in the organic layer. Therefore, 600  $\mu\text{L}$  acetonitrile was injected into  
13  
14 202 the pipette to break down the emulsion.

### 15 16 203 **Acceptor pH and volume**

17  
18 204 In order to efficiently extract sulfonamides into the acceptor phase, the pH of acceptor phase  
19  
20 205 should ionize the trapped analytes to prevent them from being back-extracted into the organic phase.  
21  
22 206 The alkaline acceptor phase was investigated using NaOH solution in the range of 0.005-0.5 mol/L. It  
23  
24 207 can be seen from Figure 6 that 0.1 mol/L NaOH of acceptor solution presented satisfactory results. Thus  
25  
26 208 0.1 mol/L NaOH was used as the acceptor phase.

27  
28 209 Size of the acceptor droplet plays an important role in back-extraction of analyte from the organic  
29  
30 210 phase. The size also influences the enrichment factor by changing the volume ratio of the donor to the  
31  
32 211 acceptor phase. Volume of 0.1 mol/L NaOH acceptor was examined in the range of 1-5  $\mu\text{L}$  in a test trial.  
33  
34 212 As the obtained results shown, larger droplets provided higher signal intensity of the analytes. More  
35  
36 213 target molecules will move into the acceptor phase through the surface of the large droplet in a certain  
37  
38 214 time than the small one. However, it was found that the NaOH droplets larger than 4  $\mu\text{L}$  are unstable in  
39  
40 215 the organic layer of 1-octanol. Subsequently 3  $\mu\text{L}$  of acceptor phase using 0.1 mol/L NaOH solution was  
41  
42 216 preferred in this work.

### 43 217 **Extraction time**

44  
45 218 In the proposed method, the extraction consists of DLLME pre-extraction and SDME  
46  
47 219 back-extraction. DLLME pre-extraction time means the time interval from the beginning of the  
48  
49 220 dispersion and its end just before injection of the demulsifier solvent. The effect of DLLME time was  
50  
51 221 examined in the range of 1-20 min. As showed in Figure 7-A, DLLME time longer than 2 min has no  
52  
53 222 significant enhancement on the extraction efficiency of sulfonamides, because the rate of extraction in  
54  
55 223 DLLME is extremely fast. In the following experiments, DLLME time of 2 min was adopted.

56  
57 224 The effect of SDME back-extraction time on the extraction efficiency was examined in the range  
58  
59  
60

1  
2  
3  
4 225 of 2-20 min. As observed in Figure 7-B, the peak area of sulfonamides reached equilibrium after 15 min.  
5  
6 226 It indicates that the mass-transfer of SDME back-extraction in this LLLME is noticeably faster than the  
7  
8 227 conventional SDME. There are two reasons for this. The first is that a high concentration gradient of  
9  
10 228 analyte in the organic phase to the acceptor phase has been contributed by the fast and effective  
11  
12 229 DLLME pre-extraction. The second is that the volume ratio of the aqueous acceptor droplet to the  
13  
14 230 organic donor layer is much larger than that in conventional SDME (the organic extraction droplet to the  
15  
16 231 bulk of the aqueous solution). Because the volume of the 1-octanol layer here is only about 200  $\mu\text{L}$   
17  
18 232 rather than 4-10 mL usually applied in conventional SDME for the volume of aqueous sample.  
19  
20 233 Consequently, the SDME time was set at 15 min.

21  
22 234 So the new LLLME combined a 2-min DLLME pre-extraction with a 15-min SDME  
23  
24 235 back-extraction. Other suitable extraction conditions for the LDS-SD-DLLME-SDME method were as  
25  
26 236 follows: the sample solution contained 0.05 mol/L  $\text{NaH}_2\text{PO}_4$  (pH 4.5) and 2 mol/L  $\text{Na}_2\text{SO}_4$ ; the  
27  
28 237 extraction emulsion was generated by injection of 200  $\mu\text{L}$  1-octanol as extraction solvent and 750  $\mu\text{L}$   
29  
30 238 methanol as disperser solvent into the aqueous phase and then demulsified by addition of 600  $\mu\text{L}$   
31  
32 239 acetonitrile after 2 min of DLLME pre-extraction; a 3  $\mu\text{L}$  droplet of 0.1 mol/L NaOH was served for the  
33  
34 240 acceptor phase.

#### 241 **Method validation**

242 The analytical performance of the proposed method under optimum conditions was validated  
243 through linearity (linear range and correlation coefficient), sensitivity (limits of detection), precision  
244 (expressed as relative standard deviation) and extraction efficiency (enrichment factors). The results are  
245 summarized in Table 2. The linear dynamic range (LDR) was 1 - 500  $\mu\text{g/L}$  for SMZ and SMX, 5 - 500  
246  $\mu\text{g/L}$  for STZ, and 10 - 500  $\mu\text{g/L}$  for SN, respectively, with the coefficient of determination ( $R^2$ ) better  
247 than 0.9993. The limit of detections (LODs) for all target sulfonamides were calculated by the  
248 signal-to-noise (S/N) ratio of three and varied between 0.22 and 1.92  $\mu\text{g/L}$ . The reproducibility was  
249 studied from five replicated experiments for spiked solution (50  $\mu\text{g/L}$  SN, 50  $\mu\text{g/L}$  STZ, 5  $\mu\text{g/L}$  SMZ, 5  
250  $\mu\text{g/L}$  SMX). The intra-day relative standard deviation (RSD,  $n=5$ ) was lower than 4.2% and the  
251 inter-day relative standard deviation (RSD,  $n=3$ ) was lower than 4.6%. The enrichment factors of 6, 19,  
252 55, and 91 for SN, STZ, SMZ, and SMX, respectively, were evaluated by comparing the calibration

1  
2  
3  
4 253 graphs before and after the extraction process. It as can be seen from the Table 1 that the sequence of  
5  
6 254 enrichment factors were in consistence with the logD values of the tested sulfonamides.  
7

8 255 Comparison of the proposed technique with other microextraction techniques was presented in  
9  
10 256 Table 3. As can be seen, LODs, RSD, LDR and EF of the presented method were comparable with the  
11  
12 257 other methods in our comparison. In addition, the extraction time of the proposed method had a  
13  
14 258 significant advantage compared with conventional LLLME methods.  
15

### 16 259 **Environmental water sample analysis**

17  
18 260 The procedure was applied to the analysis of sulfonamides in the lake, fishery and wastewater  
19  
20 261 samples, and no target analytes were found in these samples. Then, spiked sulfonamides in real water  
21  
22 262 samples were determined to assess the matrix effect. As given in Table 4, the relative recoveries of the  
23  
24 263 targets were in the range of 85.9 % - 105.8 %. It demonstrated that the method was suitable for the  
25  
26 264 determination of trace sulfonamides in the environmental water samples. The typical chromatograms of  
27  
28 265 the non-spiked and spiked fishery water sample obtained by this method were shown in Figure 8  
29  
30 266 (spiking 5 µg/L for SMZ and SMX; 50 µg/L for SN and STZ).  
31

### 32 267 **Conclusion**

33  
34 268 In general, low-density solvent-based solvent-demulsification dispersive liquid-liquid  
35  
36 269 microextraction (LDS-SD-DLLME) combined with single-drop microextraction (SDME) was  
37  
38 270 developed and for the first time applied for the determination of sulfonamides in environmental water  
39  
40 271 samples. The convenient LDS-SD-DLLME-SDME coupling avoids the typical centrifugation in  
41  
42 272 DLLME, stirring step in SDME and LLLME, therefore the pretreatment does not need any electric  
43  
44 273 device (centrifuge, stirrer or ultrasonic cleaner) in the whole extraction procedure, which simplifies the  
45  
46 274 operation and speeds up the pretreatment of samples. The extreme simplicity, wiring needlessness, high  
47  
48 275 speed and efficiency of the proposed method offers the opportunity to perform the sample pretreatments  
49  
50 276 in the field.

## Tables

**Table 1.**

Structure, log D and pKa values of target sulfonamides

Sulfonamides	Sulfanilamide (SN)	Sulfathiazole (STZ)	Sulfamethazine (SMZ)	Sulfamethoxazole (SMX)
CAS No.	63-74-1	72-14-0	57-68-1	723-46-6
Structure				
logD	-0.67	0.045	0.29	0.64
pKa <sub>1</sub>	1.85 ± 0.10	2.19 ± 0.10	1.69 ± 0.10	1.39 ± 0.10
pKa <sub>2</sub>	10.10 ± 0.10	7.24 ± 0.10	7.89 ± 0.10	5.81 ± 0.50

LogD and pKa are calculated using Advanced Chemistry Development (ACD/Labs) Software V11.02 (©1994-2011 ACD/Labs), which are from Scifinder Scholar.

**Table 2.**

Analytical characteristics of the proposed method for the determination of sulfonamides.

Analytes	Calibration curve ( $\mu\text{g/L}$ )	$R^2$	Linear range ( $\mu\text{g/L}$ )	LOD ( $\mu\text{g/L}$ )	EF	Intra-day RSD <sup>a</sup> %	Inter-day RSD <sup>b</sup> %
SN	$y=0.0975x-0.5586$	0.9993	10-500	1.92	6	4.2	4.0
ST	$y=0.2096x-0.6529$	0.9998	5-500	0.88	19	3.5	4.6
SM2	$y=0.7258x-2.6558$	0.9999	1-500	0.27	55	3.9	1.3
SMO	$y=1.2073x-2.2077$	0.9999	1-500	0.22	91	0.8	2.5

<sup>a</sup>: n=5, SN and STZ are 50  $\mu\text{g/L}$ , SMZ and SMX are 5  $\mu\text{g/L}$ .<sup>b</sup>: n=3, SN and STZ are 50  $\mu\text{g/L}$ , SMZ and SMX are 5  $\mu\text{g/L}$ .

**Table 3.**

Comparison of the presented method for the determination of sulfonamides with other microextraction techniques.

Analyte	Method	Extraction time (min)	LOD ( $\mu\text{g/L}$ )	EF	Ref
STZ, SMZ, SMX	LLLME/AMADP <sup>d</sup> -HPLC-UV	45	0.11-0.77	-	1
SMZ, SMX	ILs-MADLLME <sup>b</sup> -HPLC-FLD	15	0.015-0.014	28-37	8
STZ, SMZ	Salting-out LLE-HPLC-UV	11	3.8-4.5	-	17
SMX	CPE-HPLC-UV	30	6.56	-	18
SMZ, SMX	HF-LPME-HPLC-UV	480	0.1-0.3	73-100	34
STZ, SMX	SPME-LC-MS/MS	50	14.0-26.3	-	41
SMZ, SMX	SBSE-LD <sup>a</sup> -HPLC/DAD	100	1.29-1.85	-	42
SMX	PPG <sub>400</sub> -salt ATPS <sup>c</sup> -HPLC-FLD	40	0.1	-	43
SN, STZ	LDS-SD-DLLME-SDME <sup>e</sup> -HPLC-UV	17	0.88, 1.92	6, 19	This work
SMZ, SMX			0.22, 0.27	55, 91	

<sup>a</sup>: SBSE-LD: Stir bar sorptive extraction and liquid desorption.

<sup>b</sup>: ILs-MADLLME: Ionic liquids-based microwave-assisted DLLME.

<sup>c</sup>: PPG<sub>400</sub>-salt ATPS: Poly (propylene glycol) <sub>400</sub>-salt aqueous two- phase system.

<sup>d</sup>: LLLME/AMADP: LLLME in utilizing automated movement of acceptor and donor phase.

<sup>e</sup>: LDS-SD-DLLME-SDME: low-density solvent-based solvent-demulsification dispersive liquid-liquid microextraction single-drop microextraction.

**Table 4.**

Summary of recovery study performed on spiked water samples.

Analytes	Added ( $\mu\text{g L}^{-1}$ )	South Lake water		Fishery water		Wastewater	
		Recovery (%)	RSD (%)	Recovery (%)	RSD (%)	Recovery (%)	RSD (%)
SN	50	96.6	1.5	105.8	3.4	95.0	2.1
STZ	50	100.7	2.7	101.0	3.6	95.0	1.0
SMZ	5	95.2	4.6	99.3	4.8	85.9	6.2
SMX	50	96.5	6.3	104.3	4.9	98.2	3.6
	5	96.2	3.9	86.8	4.0	87.6	2.6
	50	99.7	2.1	102.1	6.1	94.2	3.1

## Figure captions

**Figure 1.** The LDS-SD-DLLME-SDME procedure.

Steps (a) and (b) injecting extractant and disperser solvent into the donor phase (pH 4.5) that generates a cloudy solution; (c) adding acetonitrile to break down the emulsion; (d) after phase separation the organic phase going to the upper layer; and (e) suspending an acceptor droplet in the organic phase for back-extraction.

**Figure 2.** Effect of phase separation method on extraction of sulfonamides.

Aqueous sample: 500 µg/L SAs, 0.05 mol/L NaH<sub>2</sub>PO<sub>4</sub>, no Na<sub>2</sub>SO<sub>4</sub>; Organic solvents: 500 µL methanol and 200 µL 1-octanol; Acceptor solution: 3 µL 0.01 mol/L NaOH; Extraction time: 2 min DLLME, 10 min SDME.

**Figure 3.** Effect of extraction solvent on extraction of sulfonamides

Organic solvents: 250 µL toluene, 235 µL iso-octanol, 225µL decanol, or 235 µL 1-octanol; other conditions are same to Figure 1.

**Figure 4.** Effects of salt addition (A) and Na<sub>2</sub>SO<sub>4</sub> concentration (B) on extraction of sulfonamides.

**Figure 5.** Effect of demulsifier solvent (A) and acetonitrile volume (B) on extraction of sulfonamides

Sample solution: 500 µg/L SAs, 0.05 mol/L NaH<sub>2</sub>PO<sub>4</sub>, 2 mol/L Na<sub>2</sub>SO<sub>4</sub>; Organic solvents: 750 µL methanol and 200 µL 1-octanol; Acceptor solution: 3 µL 0.1 mol/L NaOH; Extraction time: 2 min DLLME, 10 min SDME.

**Figure 6.** Effect of NaOH concentration on extraction of sulfonamides.

Sample solution: 500 µg/L SAs, pH 4.5, 0.05 mol/L NaH<sub>2</sub>PO<sub>4</sub>, 2 mol/L Na<sub>2</sub>SO<sub>4</sub>; Organic solvents: 750 µL methanol and 200 µL 1-octanol; Acceptor solution: 3 µL 0.1 mol/L NaOH; Extraction time: 2 min DLLME, 15 min SDME.

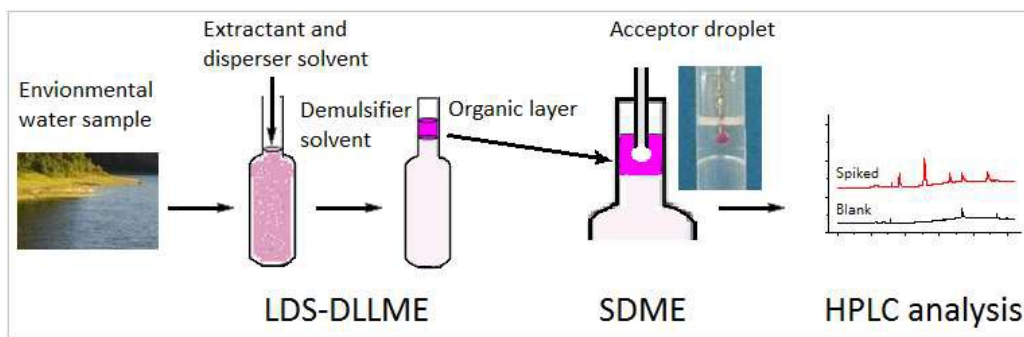

**Figure 7.** Effect of DLLME time (A) and SDME time (B) on extraction of sulfonamides.

**Figure 8.** Chromatograms the non-spiked (blank) and the spiked fishery water sample.

Sample solution: pH 4.5, 0.05 mol/L NaH<sub>2</sub>PO<sub>4</sub>, 2 mol/L Na<sub>2</sub>SO<sub>4</sub>; spiked sample: 5 µg/L for SMZ and SMX; 50 µg/L for SN and STZ. Organic solvents: 750 µL methanol and 200 µL 1-octanol. Acceptor solution: 3 µL 0.1 mol/L NaOH. Extraction time: 2 min DLLME, 15 min SDME.

## Figures

## TOC Art

A simple coupling of low-density solvent-based solvent-demulsification dispersive liquid-liquid microextraction (LDS-SD-DLLME, 2-min pre-extraction) and single-drop microextraction (SDME, 15-min back-extraction) was developed for the determination of sulfonamides in environmental water samples for the first time.
