**Determination of Low Levels of Cd(II) in Cosmetic Products by Spectrophotometry  
after Separation/Preconcentration with Cloud Point Extraction**

Nail Altunay<sup>1,\*</sup> and Ramazan Gürkan<sup>1</sup>

**Abstract**

In the present study, a simple, low-cost and efficient method was developed for extraction and preconcentration of Cd(II) from cosmetic products by using cloud point extraction (CPE) prior to spectrophotometric detection. The method is based on ternary complex formation of Cd(II) ions with 2',7'-dichlorofluorescein (DCIF) in presence of 2,2'-bipyridine (Bipy) and NaCl as chelating and salting-out agents at pH 7.0 respectively, and then its extraction into the micellar phase of polyethylene glycol *tert*-octylphenyl ether (Triton X-114). The effects of various variables affecting complex formation and CPE efficiency were investigated and optimized. The calibration graph was highly linear in the range of 8-120  $\mu\text{g L}^{-1}$  with a good regression coefficient, in which the absorbance is decreased with increase in concentration of Cd(II) at 502 nm. The limits of detection and quantification were 2.5 and 8.3  $\mu\text{g L}^{-1}$  with a sensitivity enhancement factor of 31.4, respectively. The relative standard deviations (RSDs) were in range of 2.5-5.1 % (for 15, 30 and 60  $\mu\text{g L}^{-1}$ , n: 5). The recovery rates of spiked samples were in the range of 97.2-103 % (15, 30 and 60  $\mu\text{g L}^{-1}$ , n: 5). Its accuracy was controlled by analysis of a certified reference material (CRM 1548a Typical Diet). It has been observed that the result for Cd(II) is statistically within 95 % confidence limit for certified value. The results show that the proposed method can be applied satisfactorily to determine Cd(II) in cosmetic products.

### 38 **Introduction**

39  
40  
41 It is now widely accepted that cadmium, Cd(II) is a highly toxic metal with many  
42 long-term effects, and is known to damage organs such as kidneys, liver and lungs, even at  
43 very low concentrations.<sup>1</sup> It is intentionally or non-intentionally used in cosmetic products as  
44 impurities in color additives. Directly contact with cosmetics is an important pathway through  
45 which Cd(II) dermally enters human body, thus there is an increasing need to monitor low  
46 levels of Cd(II) in cosmetic products. Moreover, such data can also provide us with Cd(II)  
47 contamination information about safety and quality control of product.<sup>2</sup> However, directly  
48 accurate and reliable determination of Cd(II) in cosmetic products is often difficult, not only  
49

1  
2  
3 because of low concentrations, but also because of matrix effects. To overcome these  
4  
5 problems, separation–preconcentration procedures are often involved prior to analysis.  
6  
7

8 Many analytical techniques such as anodic stripping voltammetry (ASV),<sup>3,4</sup> adsorptive  
9 stripping voltammetry (AdSV),<sup>5</sup> adsorptive cathodic stripping voltammetry (AdCSV),<sup>6</sup>  
10 inductively coupled plasma-mass spectrometry (ICP-MS),<sup>7</sup> inductively coupled plasma-  
11 optical emission spectrometry (ICP-OES),<sup>8</sup> neutron activation analysis (NAA),<sup>9</sup>  
12 electrothermal atomic absorption spectrometry (ET-AAS)<sup>10</sup> and flame atomic absorption  
13 spectrometry (FAAS)<sup>11</sup> have been developed to determine low levels of Cd(II) in different  
14 samples. Each of these techniques has its own peculiar privileges, but each method has some  
15 problems such as poor reproducibility and limited sample adaptability. Among these sensitive  
16 techniques, instruments such as ET-AAS, ICP-OES and ICP-MS are useful for trace Cd(II)  
17 determination without any preconcentration. However, these instruments are more expensive  
18 to buy and employ in research laboratories. Besides, these techniques have spectral and  
19 chemical interferences as well as requiring expert's user, poor precision, limited dynamic  
20 range and slower analysis time. Molecular absorption spectrophotometry in ultraviolet-visible  
21 region is a simple technique, cheap, easy to operate, rapid response time, available in many  
22 laboratories, and offers acceptable analytical figures of merit when dealing with trace levels  
23 of Cd(II) in different matrices like cosmetic products. But, due to its low detection power,  
24 there is a need to separation and preconcentration procedures in presence of a suitable  
25 absorbing reagent(s) for analyte, which can dramatically improve the detection limit as well  
26 as the selectivity of the technique.

49

50 In spite of great developments in the modern analytical instruments, available  
51 analytical instrumentation does not have enough sensitivity for the analysis of real samples.  
52 Many techniques for separation and preconcentration of Cd(II) have been proposed such as  
53 pyridine-2,6-diamine-functionalized Fe<sub>3</sub>O<sub>4</sub> nanoparticles as a novel sorbent,<sup>12</sup> new

3 functionalized resin,<sup>13</sup> an activated carbon column,<sup>14</sup> 2-(5-bromo-2-pyridylazo)-5-  
4 diethylaminophenol (5-Br-PADAP) functionalized wool-packed microcolumn,<sup>15</sup> dispersive  
5 liquid–liquid microextraction (DLLM),<sup>16</sup> cloud point extraction (CPE),<sup>17,18</sup> solid-phase  
6  
7  
8  
9  
10 extraction (SPE),<sup>19,20</sup> liquid phase microextraction (LPME)<sup>21</sup> and electrochemical  
11  
12 deposition.<sup>22</sup> The most important of these separation and preconcentration techniques is CPE  
13  
14 procedure. CPE has been displayed to have the diverse merits of low cost, simplicity,  
15  
16 velocity, lower toxicity to the environment than extractions that use organic solvents and a  
17  
18 high capacity to concentrate a wide variety of analytes of widely varying rate with high  
19  
20 recoveries and high concentration factors. However, simple combination with spectral,  
21  
22 chromatographic, atomic absorption/emission and electro-chemical analyses allows using  
23  
24 CPE for elaborating high-sensitive and convenient analytical methods.<sup>23</sup> When it is chosen a  
25  
26 sensitive and selective reagent like 2',7'-dichlorofluorecein (DCIF), spectrophotometry is  
27  
28 becoming one of the most widely used techniques for accurate and reliable determination of  
29  
30 trace Cd(II) after separation and preconcentration with CPE.  
31  
32

33  
34 In this sense, the aim of the present work was, on one hand, to propose a CPE method  
35  
36 based on the use of Triton X-114 for extraction of Cd(II) as ternary complex and, on the other  
37  
38 hand, to evaluate the combination of the proposed CPE procedure with spectrophotometry for  
39  
40 trace metal analysis. To this end, the analytical variables affecting the complex formation and  
41  
42 CPE efficiency were optimized in detail. Under the optimized CPE conditions, analytical  
43  
44 figures of merit of the method were estimated, in which the absorbance is decreased with  
45  
46 increase in concentration of Cd(II) at 502 nm. The method accuracy was assessed through the  
47  
48 analysis of a certified reference material (CRM 1548a typical diet), and the result was in  
49  
50 agreement with the certified value at a 95 % confidence level according to Student *t*-test.  
51  
52  
53 Finally, cosmetic products were analyzed in order to assess the applicability of the method to  
54  
55 analysis of real time samples.

## Experimental

### Instrumentation

Absorbance measurements were made at 485 and 502 nm before and after preconcentration with CPE by using a double beam UV-Visible spectrophotometer (Shimadzu UV-1800 PC, Kyoto, Japan) equipped with the 1.0-cm quartz cells. A thermostatic water bath (EPC 4420, Termal, and Istanbul, Turkey) was used to maintain the temperature in CPE experiments. A centrifuge (Universal-320, England) was used to accelerate the phase separation process. The pH measurements were carried out with a pH meter (pH-2005, JP Selecta, Barcelona, Spain).

### Reagents and solutions

All chemicals and reagents used were of analytical-reagent grade or higher purity. All solutions were prepared with deionized water (18.2 M $\Omega$  cm) obtained from a Labconco (Kansas City, USA) water purification system. The working solutions of Cd(II) for calibration were prepared by dilution of the stock solution of 1000 mg L<sup>-1</sup> supplied from Merck (Darmstadt, Germany) water just before use. The solutions of 5.0 % (v/v) of Triton X-114 (Sigma-Aldrich, Milwaukee, USA) were prepared by dissolving 5.0 mL of surfactant in water and diluting to 100 mL in a volumetric flask. DCIF (1.0 $\times$ 10<sup>-3</sup> mol L<sup>-1</sup>) and Bipyr (0.01 mol L<sup>-1</sup>) solutions were prepared by dissolving their appropriate amounts (Sigma-Aldrich, Milwaukee, USA) in ethanol and completing to 1 L with water. The NaCl solution of 0.01 mol L<sup>-1</sup> as salting-out agent was prepared by dissolving 0.0578 g of solid in water and completing to 100 mL in a volumetric flask. The vessels and pipettes used for trace analysis were kept in 10 % (w/v) HNO<sub>3</sub> for at least 24 h and subsequently washed five times with deionized water.

### Sampling and sample preparation

1  
2  
3 The cosmetic samples were purchased from local open-markets and in a Turkish store  
4 in Sivas, Turkey where it is suitable to buy cheap cosmetic products such as shampoo, nail  
5 polish, lipstick. An aliquot of 2 g or 5 mL of each semi-solid and/or liquid cosmetic products  
6 was transferred into a Pyrex glass beaker of 100 mL and digested with 5 mL of concentrated  
7 HNO<sub>3</sub> (65 %, w/w) on a heater at 80 °C until samples dried. This process was repeated five  
8 times. Then, 4 mL of a mixture of HNO<sub>3</sub> (65 %, w/w) and HClO<sub>4</sub> (70 %, w/w) and H<sub>2</sub>O<sub>2</sub> (30  
9 %, w/w) (in volume ratio of 2:1:1, v/v)<sup>24</sup> was added for oxidizing entirely the organic matrix.  
10 The mixture was covered and left to stand overnight, and then heated to 125 °C for 1 h. Until  
11 a clear homogenous solution is obtained, again 4.0 ml of mixture of concentrated acids were  
12 added to the sample solutions when necessary. After that, the digested samples were  
13 immediately cooled in an ice-cooler and filtered through a 0.21-µm-pore size polycarbonate  
14 membrane filter (Nuclepore, Whatman, Brentford, UK). The separated solutions were diluted  
15 to the final volume of 50 mL with water. The Cd(II) contents of the pretreated cosmetic  
16 samples were determined by help of both direct calibration curve and standard addition  
17 calibration curve approaches based on spectrophotometric detection at 502 nm after  
18 preconcentration with CPE. An aliquot of 1.0 g of a certified reference material, CRM 1578a  
19 typical diet, for validation of the method was placed into a PTFE beaker. The certified sample  
20 was pretreated and digested at the same time as the cosmetics, using the same conditions and  
21 acid mixture. Although the certified sample is not a cosmetic matrix, it has some of the same  
22 components. The fat content may not be comparable to all of the skin cream or lipstick types,  
23 depending on their formulation. Also, a blank analysis was carried out following the same  
24 procedure without cosmetic sample. In order to control a possible systematic error arising  
25 from matrix effect, standard Cd(II) solutions at levels of 10 and 15 µg L<sup>-1</sup> above the method  
26 quantification limit were spiked into 3-5 mL of the pretreated cosmetic samples under the  
27 optimized conditions as well as the certified sample, and the recoveries of spiked samples

3 were established. Each sample was analyzed in triplicate, and reagent blank determination  
4  
5 was performed to ascertain that no impurity was introduced during the extraction procedure.  
6

### 7 8 **The CPE procedure**

9  
10 In the proposed method, aliquots of sample or pretreated-sample containing Cd(II) in  
11 the range of 8–120  $\mu\text{g L}^{-1}$ , 1.0 mL of 0.01 mol  $\text{L}^{-1}$  pH 7.0 Tris/HCl buffer, 3.0 mL of 0.01 mol  
12  $\text{L}^{-1}$  Bipy, 7.0 mL of  $1.0 \times 10^{-3}$  mol  $\text{L}^{-1}$  DCIF, 0.3 mL of 5.0 % (v/v) Triton X-114, 3.0 mL of  
13  
14 0.01 mol  $\text{L}^{-1}$  NaCl respectively, were added into a 50 mL centrifuge tube and volume was  
15  
16 completed to 50 mL with deionized water. The solutions were mixed well and kept in a  
17  
18 thermostatic water bath for 8 min at 50 °C. The phase separation was expedited by  
19  
20 centrifuging at 3500 rpm for 10 min. The resulting mixtures were cooled in an ice-bath for 10  
21  
22 min to increase the viscosity of the surfactant-rich phase and make easy the separation of the  
23  
24 aqueous phase. The aqueous phase was easily separated from surfactant-rich phase by  
25  
26 inverting the tube. The surfactant-rich phase was diluted to 1.0 mL with tetrahydrofuran  
27  
28 (THF). The absorbance of the solution was measured at 502 nm. A blank solution (without  
29  
30 Cd(II)) was also submitted to the same procedure and measured in parallel to the samples.  
31  
32  
33  
34  
35

### 36 **Results and Discussion**

#### 37 38 **General aspects related to method development**

39  
40 Prior to optimization of analytical variables affecting CPE efficiency, at initial, Job's  
41  
42 continuous variation method<sup>25</sup> was used to determine the stoichiometric ratio and stability  
43  
44 constant of ternary complex. With this aim, the mixtures were prepared by mixing solutions  
45  
46 of both components, Cd(II) and DCIF, with equal molar concentration ( $1.0 \times 10^{-4}$  mol  $\text{L}^{-1}$ ) in  
47  
48 ratio varying from 1:9 to 9:1. The absorbance of ternary complex formed has been  
49  
50 independently measured in presence of Bipy and NaCl of  $6.0 \times 10^{-4}$  mol  $\text{L}^{-1}$  at 502 and 485  
51  
52 nm with and without CPE, respectively. At pH 6.0, the stability constant has been found to be  
53  
54  $2.3 \times 10^4$  with a stoichiometric ratio of 2.15 in aqueous alcoholic media at 485 nm, which is  
55  
56  
57  
58  
59  
60

1  
2  
3 lower than the value determined in aqueous micellar media at 502 nm with a red shift of 17  
4 nm after preconcentration with CPE. The stability constant after preconcentration with CPE at  
5 pH 7.0 is  $8.6 \times 10^5$  with stoichiometric ratio of 1.95, these values prove that the ternary  
6 complex is more stable in aqueous micellar media. It has been implied by that it can be  
7 selectively used as a fluorescent sensor for Cd(II) ions in presence of  $\text{Cu}^{2+}$ ,  $\text{Zn}^{2+}$  and  $\text{Ni}^{2+}$  ions  
8 in literature,<sup>26</sup> in which two Cd(II) ions are directly bonded to DCIF with a value  $\log\beta = 3.80$   
9 in absence of Bipyridine. Due to a  $\text{p}K_{\text{hydrolysis}}$  of 10.15 for Cd(II), in form of  $\text{CdCl}^+ + \text{H}_2\text{O} \leftrightarrow$   
10  $\text{Cd}(\text{OH})\text{Cl} + \text{H}^+$  in range of pH 7.0-9.0,<sup>27</sup> it can be also concluded that chloride ions as  
11 salting-out agent will directly be able to participate into the complexation in presence of DCIF  
12 and 2,2'-bipyridine (Bipyridine) at pH 7.0.<sup>28</sup> In this sense, the mixtures were prepared by mixing  
13 solutions of Cd(II) and Bipyridine, with equal molar concentration ( $5.0 \times 10^{-4} \text{ mol L}^{-1}$ ) in ratio  
14 varying from 1:9 to 9:1. The absorbance of ternary complex formed has been measured in  
15 presence of DCIF and NaCl of  $1.5 \times 10^{-4} \text{ mol L}^{-1}$  at 502 and 485 nm with and without CPE,  
16 respectively. It has been observed that a stoichiometric ratio,  $[\text{Cd}(\text{II})]/[\text{Bipyridine}]$  is 1:2 in aqueous  
17 micellar media at 502 nm while it is 1:1 in aqueous alcoholic media at 485 nm. The  
18 absorbance signals are lower than those in presence of Bipyridine without Bipyridine at both 502 nm  
19 and 485 nm. As a result of increased electron density on Cd(II) ions in coordination center,  
20 the coordination number expanded from 4 to 6 by adding neutral electron donor nitrogenous  
21 ligand, Bipyridine, so as to give a more stable, sensitive and selective hydrophobic complex, which  
22 can be easily extracted into the micellar phase. Moreover, a red shift of 17 nm from 485 nm to  
23 502 nm can be also an indicator of increased electron density on the cadmium in ternary  
24 complex. This state can be explained by means of only to charge transfer transitions from  
25 ligand to Cd(II) ions, due not to be d-d transitions for Cd(II) with configuration of  $d^{10}$ .  
26 Therefore, depending on pH, temperature and concentrations of DCIF, Bipyridine and NaCl in  
27 presence and absence of extracting nonionic surfactant, Triton X-114 above critical micelle

2  
3 concentration, it is believed that the ternary complex formed is in form of octahedral  
4 geometry for the method with preconcentration at 502 nm while it is in form of tetrahedral  
5 geometry for the method without preconcentration at 485 nm, in which the optimal conditions  
6 for Cd(II) in range of 100-1500  $\mu\text{g L}^{-1}$  are .2.5 mL of 0.01 mol  $\text{L}^{-1}$  Bipyr, 5.0 mL of  $1.0 \times 10^{-3}$   
7 mol  $\text{L}^{-1}$  DCIF, 2.5 mL of 0.01 mol  $\text{L}^{-1}$  NaCl and 2.5 mL of 0.05 mol  $\text{L}^{-1}$  phosphate buffer in a  
8 volumetric flask of 50 mL for equilibrium temperature of 40 °C for 15 min at pH 6.0. As a  
9 result, this mechanism of ternary complex formation with tetrahedral and octahedral  
10 geometries can be postulated as follows:  
11

### 20 **Optimization of the CPE system variables**

21  
22 The effects of concentrations of reagents and nonionic surfactant, pH, temperature and  
23 time of equilibration, centrifugation rate and time on the analytical signal were investigated  
24 and optimized in order to reach the best analytical performance for the CPE procedure. Fig. 1  
25 shows the change in absorption of the ternary complex formed in presence of DCIF, Bipyr  
26 and NaCl in surfactant-rich phase against reagent blank with increasing Cd(II) concentration  
27 at levels of 25, 50 and 75  $\mu\text{g L}^{-1}$  at pH 7.0.  
28  
29  
30

32  
33  
34  
35

36 The pH is evaluated as a critical factor to increase the partition coefficient of the  
37 analyte between aqueous and surfactant-rich phase which lead to increase the extraction  
38 efficiency. Therefore, the effect of pH on extraction efficiency of Cd(II) was investigated in  
39 pH range of 5-10 by using different buffers such as Tris/HCl,  $\text{NH}_3/\text{NH}_4\text{Cl}$ ,  $\text{H}_2\text{PO}_4^-/\text{HPO}_4^{2-}$  and  
40 borate at iso-molar concentrations. The absorbance of surfactant-rich phase containing Cd(II)  
41 at level of 50  $\mu\text{g L}^{-1}$  was measured at 502 nm. The best sensitivity was obtained with Tris/HCl  
42 buffer at pH 7.0. As can be seen in Fig. 2(a), increase of pH up to 7.0 leads to an increase in  
43 absorbance and then gradually decreases. The decrease in extraction efficiency at higher pHs  
44 than 7.0 may be due to hydrolysis of Cd(II) ions, so as to give further  $\text{Cd}(\text{OH})_2$  and  $\text{Cd}(\text{OH})_3^-$   
45 species. Also, the effect of buffer concentration on the extraction efficiency was studied in the  
46  
47  
48

59  
60

1  
2  
3 range of  $(0.05-1.4)\times 10^{-3}$  mol L<sup>-1</sup> concentration in Fig. 2(b), and the best analytical signal was  
4  
5 obtained with using  $0.2\times 10^{-3}$  mol L<sup>-1</sup> of buffer solutions. In higher concentrations than  
6  
7  $0.2\times 10^{-3}$  mol L<sup>-1</sup>, the decrease in absorbance may be due to inhibition effect of excess neutral  
8  
9 Tris buffer with a pK<sub>a</sub> value of 8.1, so as to give a cationic complex with Cd(II) ions from  
10  
11 potentiometric titration data ( $\log K_{\text{Cd}(\text{tris})2+} = 1.94\pm 0.02$  at 25 °C).<sup>29</sup> Therefore, a buffer  
12  
13 concentration of  $0.2\times 10^{-3}$  mol L<sup>-1</sup> at pH 7.0 was used as optimal value for further studies.

14  
15  
16 The variation of absorbance as a function of the concentration of Bipyr as main chelating  
17  
18 ligand was studied in the range of  $(0.06-1.0)\times 10^{-3}$  mol L<sup>-1</sup>. From the results in Fig. 3(a), it can  
19  
20 be seen that the absorbance linearly increases with increasing Bipyr concentration up to  
21  
22  $0.6\times 10^{-3}$  mol L<sup>-1</sup>. The absorbance partly decreases at the higher concentrations than  $0.6\times 10^{-3}$   
23  
24 mol L<sup>-1</sup>. So, a Bipyr concentration of  $0.6\times 10^{-3}$  mol L<sup>-1</sup> was selected as optimal value for  
25  
26 further studies.  
27  
28  
29

30  
31 The effect of DCIF concentration as ion-association reagent on extraction efficiency was  
32  
33 studied in range of  $(0.02-0.20)\times 10^{-3}$  mol L<sup>-1</sup>. As can be seen in Fig. 3(b), it is clear that  
34  
35 absorbance dramatically depends on the concentration of DCIF in CPE procedure. With the  
36  
37 increase in concentration of DCIF, the absorbance linearly increases up to  $0.14\times 10^{-3}$  mol L<sup>-1</sup>  
38  
39 with increasing concentration and then slowly decreases. This decrease may be due to  
40  
41 aggregation of ion-association ligand. Therefore, a concentration of  $0.14\times 10^{-3}$  mol L<sup>-1</sup> was  
42  
43 selected as optimal value for further studies.  
44  
45

46  
47 Optimization of nonionic surfactant as extracting agent was carried out in order to use a  
48  
49 minimum surfactant concentration with maximum extraction efficiency. The effect of Triton  
50  
51 X-114 concentration on the absorbance of ternary complex was studied in the range of 0.01-  
52  
53 0.5 % (v/v). From the results in Fig. 4, it can be seen that the absorbance increases up to 0.3 %  
54  
55 (v/v), and then gradually decreases. At lower concentrations than 0.3 % (v/v), the extraction  
56  
57 efficiency is slightly lower probably due to inadequacy of the assemblies to entrap the  
58  
59  
60

1  
2  
3 hydrophobic complex quantitatively. At higher concentrations than 0.3 % (v/v), the decrease  
4  
5 in absorbance may be due to the increment in the volumes and the viscosity of the surfactant  
6  
7 phase. Therefore, a concentration of 0.3 % (v/v) was selected as the optimal for further  
8  
9 studies.

10  
11  
12 Equilibrium temperature and incubation time are two important parameters in CPE. The  
13  
14 effects of equilibration temperature and incubation time on the absorbance were studied in the  
15  
16 range of 20–70 °C and 0–20 min, respectively. Since it is desirable to employ the shortest  
17  
18 equilibration time and the lowest possible equilibration temperature, a temperature of 50 °C  
19  
20 and an equilibration time of 8 min were chosen for further studies. The effect of  
21  
22 centrifugation time upon extraction efficiency at 3500 rpm was studied for time interval of 5–  
23  
24 30 min. A centrifugation time of 10 min was selected for the entire procedure since analyte  
25  
26 extraction during this time interval is almost quantitative.

27  
28  
29  
30  
31 In CPE, addition of salt to sample solution helps to phase separation and increases the mass  
32  
33 transfer of analyte from aqueous phase to surfactant-rich phase. Also, amounts of inorganic  
34  
35 salts lead to decrease in the cloud point temperature. Therefore, it is essential to consider the  
36  
37 secondary effect of the electrolyte, which is known as salting-out effect. Based on these  
38  
39 reasons, NaCl as salting-out agent was chosen and its effect on the extraction process was  
40  
41 investigated in the range of  $(0.02\text{--}1.0)\times 10^{-3}$  mol L<sup>-1</sup>. From the results in Fig. 5, it is clear that  
42  
43 NaCl has a positive effect on the process by decreasing the coacervate phase volume, so as to  
44  
45 lead a significant increase in absorbance. The results indicate that the absorbance increases up  
46  
47 to NaCl concentration of  $0.6\times 10^{-3}$  mol L<sup>-1</sup> and then gradually decreases. Thus, a salt  
48  
49 concentration of  $0.6\times 10^{-3}$  mol L<sup>-1</sup> was selected as optimal value for further studies.

50  
51  
52  
53  
54 The volume of the surfactant-rich phase acquired after separation and preconcentration with  
55  
56 CPE is small for spectrophotometric detection. It is very important to choose the appropriate  
57  
58  
59  
60

1  
2  
3 solvent for maximum efficiency. The effect of various diluting agents such as methanol,  
4  
5 acetonitrile, ethanol, acidic methanol, acidic ethanol, acetone and THF was studied to dilute  
6  
7 surfactant-rich phase after phase separation. As can be seen in Fig. 6, the best analytical  
8  
9 sensitivity ( $m/s_m$ ) with a good correlation coefficient was obtained by THF diluted to 1.0 mL  
10  
11 from three pointed-calibration curves obtained by using fixed Cd(II) concentrations of 15, 30  
12  
13 and 60  $\mu\text{g L}^{-1}$ . So, THF was adopted as diluting agent for further studies.

### 16 Analytical figures of merit of the method

17  
18 Important parameters such as the linear working range, accuracy (as recovery rate),  
19  
20 precision (as RSD %), sensitivity, limits of detection and quantification (LOD and LOQ),  
21  
22 preconcentration and sensitivity enhancement factors were determined to evaluate the  
23  
24 analytical performance of the preconcentration method. The analytical figures of merit of the  
25  
26 method with and without preconcentration are shown in Table 1. Under the optimized  
27  
28 conditions, a linear calibration curve in the range of 8-120  $\mu\text{g L}^{-1}$  of Cd(II) was acquired after  
29  
30 CPE. A regression equation acquired by the least squares method for preconcentration method  
31  
32 is  $A = -(5.03 \pm 0.20) \times 10^{-3} C_{\text{Cd(II)}} + 0.6172 \pm 0.0042$  with a correlation coefficient of -0.9932 (n:  
33  
34 12), where A is the absorbance at 502 nm and  $C_{\text{Cd(II)}}$  is the concentration of Cd(II) ( $\mu\text{g L}^{-1}$ ).  
35  
36 The detection and quantification limits of the method from the slope of calibration curve and  
37  
38 twelve replicate measurements of the blank were found to be 2.5 and 8.3  $\mu\text{g L}^{-1}$ , respectively.  
39  
40 The precision (as RSD %) was in range of 2.5-5.1 % (15, 30 and 60  $\mu\text{g L}^{-1}$ , n: 5). The percent  
41  
42 recoveries of spiked sample solution were in range of 97.2-103 % (15, 30 and 60  $\mu\text{g L}^{-1}$ , n: 5).  
43  
44 The sensitivity enhancement factor, which is calculated by using the ratio of the slopes of  
45  
46 calibration curves obtained with and without the preconcentration, was 31.4. The  
47  
48 preconcentration factor, which is described as the ratio of the initial bulk solution volume (50  
49  
50 mL) to the surfactant rich phase volume (1.0 mL), was found to be 50.

### 56 Matrix effect

1  
2  
3 The effect of foreign ions on the recovery of spiked Cd(II) was examined. Different  
4 amounts of common cations and anions in real samples were added to the test solution  
5 containing  $50 \mu\text{g L}^{-1}$  of Cd(II) and the developed methodology was applied. If an ion causes  
6 an analytical signal change more than 5.0 %, this ion can be accepted as interference species.  
7 Table 2 shows tolerance limit of different ions. These results demonstrated that large excess  
8 amounts of some common anions and cations such as  $\text{F}^-$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{NH}_4^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ , Mg(II) and  
9 Ca(II) did not interfere on the determination of trace level of Cd(II). The cations Co(II),  
10 Ni(II), Cu(II), Ag(I), Hg(II), and Fe(III) partly interfered in the determination when they were  
11 presented in a tolerance ratio ranging from 5 to 35 (foreign ion/Cd(II)); if this was the case,  
12 selective masking agents such as thiosulfate for Cu(II), Ag(I) and Hg(II) ions, citric acid and  
13 tetrasodium pyrophosphate for Ni(II), Co(II) and Fe(III) ions, due to give more stable  
14 complexes than Cd(II) with a significant improvement in tolerance ratio, were efficiently used  
15 to solve this problem.

### 32 Analytical applications

33  
34  
35  
36 The proposed CPE method was applied to the determination of Cd(II) in the pretreated  
37 cosmetic products after digestion with mixture of  $\text{HNO}_3$ ,  $\text{HClO}_4$  and  $\text{H}_2\text{O}_2$  (2:1:1, v/v). In  
38 order to validate the method, it was applied to a certified reference material, NIST CRM  
39 1548a, with Cd(II) content of  $0.035 \pm 0.0015 \text{ mg kg}^{-1}$  respectively. Using the  
40 CPE/spectrophotometric method, which is comparatively based on directly calibration curve  
41 and standard addition calibration curve approaches, the contents of Cd(II) determined in these  
42 certified samples were  $0.036 \pm 0.002$  and  $0.037 \pm 0.002 \text{ mg kg}^{-1}$  (95 % confidence interval; n: 5)  
43 respectively. When the calculated t-values are compared with the tabulated t-values in 95 %  
44 confidence level for five replicate measurements, it has been observed that the measured  
45 values for Cd(II) are statistically in good agreement with the certified values. Also, the  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 recovery experiments were carried out by spiking the cosmetic samples including CRM with  
4  
5 different amounts of Cd(II), 10 and/or 15  $\mu\text{g L}^{-1}$  before preconcentration with CPE. The  
6  
7 spiked sample solutions were analyzed in a similar way, and the percentage recoveries were  
8  
9 calculated. Table 3 shows the results obtained for five replicate measurements. The statistical  
10  
11 analysis of these results using Student's *t*-test showed that there are no significant differences  
12  
13 between actual and observed concentrations at 95 % confidence level. The slopes of the  
14  
15 standard additions graphs for the certified samples and selected cosmetic samples did not have  
16  
17 any significant difference with that of calibration graph, and also the corresponding detection  
18  
19 limits for each cosmetic sample were found to be the same as that obtained from standard  
20  
21 solutions with a lower RSD than 5.1 %. Therefore, we can conclude that there is not any  
22  
23 matrix effect arising from the sample matrices.  
24  
25  
26

27  
28 When comparatively considered its analytical figures of merit in Table 4, the results obtained  
29  
30 in the existing work allow the determination of Cd(II) at trace levels in different sample  
31  
32 matrices and may be compared with those of other works present in the literature. Costa et  
33  
34 al.<sup>30</sup> described a preconcentration factor of 13 and limit of detection of 5.0  $\mu\text{g L}^{-1}$  for the  
35  
36 determination of Cd(II) in brine samples by ICP-OES, while De Melo Gomes et al.<sup>31</sup> obtained  
37  
38 a preconcentration factor of 20, for the analysis of fuel ethanol. Pereira and Arruda<sup>32</sup>  
39  
40 described a preconcentration factor of 100 after adsorptive preconcentration for the detection  
41  
42 limits 80 and 0.17  $\mu\text{g L}^{-1}$  level by FAAS and GFAAS, respectively. Using FAAS, Bortoleto et  
43  
44 al.<sup>33</sup> obtained a preconcentration factor of 30 with a limit of determination of 2.0  $\mu\text{g L}^{-1}$  for  
45  
46 the determination of Cd(II) in nail polish samples after preconcentration onto a column  
47  
48 containing silica gel modified with Cupferron at pH 5.5. Also, the method has lower detection  
49  
50 limit than those of the atomic and molecular spectrometric methods after preconcentration  
51  
52 with biosorbent and VALLME from different matrices including CPE at 638 nm.<sup>35, 40, 41</sup> As a  
53  
54 result, a reasonable sensitivity improvement and comparable detection limit have been  
55  
56  
57  
58  
59  
60

1  
2  
3 achieved when compared to previously reported works,<sup>34, 36-39, 42-44</sup> in literature using  
4 CPE/Spectrophotometry. So, it can locally be considered as a useful analytical tool for  
5 accurate and reliable monitoring of trace Cd(II) in cosmetic products.  
6  
7  
8

## 9 10 **Conclusions**

11  
12  
13  
14 In the existing study, the CPE procedure was efficiently used as a separation and  
15 preconcentration tool to detect low levels of Cd(II) in selected cosmetic products such as  
16 shampoo, lipstick, nail polish. The coupling of CPE with spectrophotometry can be  
17 considered an alternative to sensitive, but costly, tedious, poor precise and requiring an  
18 experienced-user detection techniques such as ICP-MS, ICP-OES, CV-AAS and GF-AAS.  
19 Also, when a strongly absorbing chromophore is selected, molecular absorption spectroscopy  
20 in ultraviolet-visible region is simple, low cost and a versatile detection tool, which can be  
21 available in nearly every research laboratory. The developed preconcentration method has a  
22 linear range of 8-120  $\mu\text{g L}^{-1}$  with a detection limit of 2.5  $\mu\text{g L}^{-1}$ , preconcentration factor of 50  
23 and sensitivity enhancement factor of 31.4. The applicability of the method to cosmetic  
24 products may also provide a meaningful contribution to the literature by using a highly  
25 sensitive and selective photometric probe such as DCIF for Cd(II) ions. Moreover, the  
26 preconcentration method proposed can safely be extended to other complicated matrices. The  
27 accuracy was controlled by analysis of a certified sample, and the results obtained by direct  
28 calibration and standard addition calibration curves were statistically in good agreement with  
29 the certified value.

**Figure 1** The changes in absorption of the ternary complex formed in presence of 25, 50 and 75  $\mu\text{g L}^{-1}$  Cd(II) as a function of absorption wavelength, nm. Other experimental conditions are described under procedures.

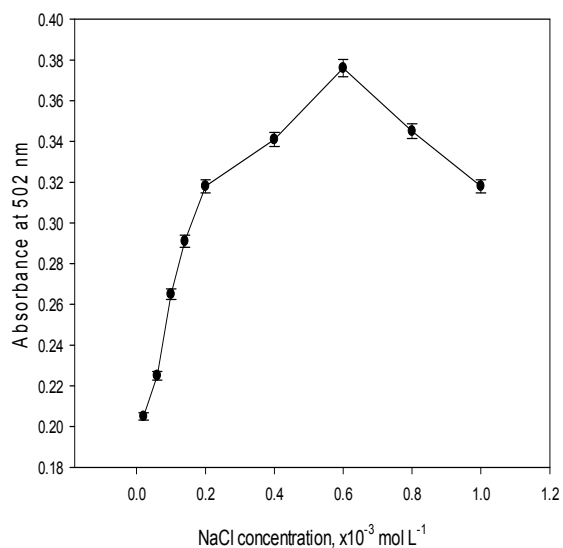

**Figure 2** Effect of (a) pH and (b) buffer concentration on CPE efficiency of 50  $\mu\text{g L}^{-1}$  Cd(II). Other experimental conditions are described under procedures.

**Figure 3** Effect of concentrations of (a) 2,2'-Bipyridine and (b) 2',7'-DCIF on CPE efficiency of  $50 \mu\text{g L}^{-1}$  Cd(II). Other experimental conditions are described under procedures.

**Figure 4** Effect of Triton X-114 concentration on CPE efficiency of  $50 \mu\text{g L}^{-1}$  Cd(II). Other experimental conditions are described under procedures.

**Figure 5** Effect of NaCl concentration as salting out agent on CPE efficiency of  $50 \mu\text{g L}^{-1}$  Cd(II). Other experimental conditions are described under procedures.

**Figure 6** Selection of diluent agent type giving the best analytical sensitivity for calibration curves obtained from three replicate measurements of  $15$ ,  $30$  and  $60 \mu\text{g L}^{-1}$  of Cd(II) for surfactant-rich phase. Other experimental conditions are described under procedures.

**Scheme 1** The possible ternary Cd(II)-DCIF-Bipyr complex formation mechanism in aqueous alcoholic and aqueous micellar media with (a) tetrahedral and (b) octahedral geometries for the methods before and after preconcentration with CPE at 485 and 502 nm under the optimized reagent conditions, respectively

**Table 1** The Analytical figures of merit for the proposed CPE/spectrophotometric method

Parameter	With DCIF	
	With preconcentration at 502 nm	Without preconcentration at 485 nm
Linear working range	8–120 $\mu\text{g L}^{-1}$	100–1500 $\mu\text{g L}^{-1}$
Slope	$-(5.03 \pm 0.20) \times 10^{-3}$	$-(1.60 \pm 0.12) \times 10^{-4}$
Intercept	0.6172 $\pm$ 0.0042	0.5782 $\pm$ 0.0036
Correlation coefficient (r)	-0.9932	-0.9998
Recovery % (n: 5)	97.2-103 (15, 30 and 60 $\mu\text{g L}^{-1}$ )	98.6-103 (150, 500 and 1000 $\mu\text{g L}^{-1}$ )
Precision, RSD (%) (n: 5)	2.5-5.1 (15, 30 and 60 $\mu\text{g L}^{-1}$ )	3.7- 2.6 (150, 500 and 1000 $\mu\text{g L}^{-1}$ )
Detection limit (LOD) ( $\mu\text{g L}^{-1}$ , n: 12)	2.5	28.5
Quantification limit LOQ ( $\mu\text{g L}^{-1}$ , n: 12)	8.3	95.0
<sup>a</sup> Preconcentration factor, PF	50	-
<sup>b</sup> Sensitivity enhancement factor, EF	31.4	-

<sup>a</sup>Preconcentration factor is defined as the ratio of the initial bulk solution volume to the volume of surfactant rich phase

<sup>b</sup>Sensitivity enhancement factor is calculated as the ratio of slopes of calibration curves obtained with and without preconcentration

**Table 2** Tolerance limits of interfering species in the determination of 50  $\mu\text{g L}^{-1}$  of Cd(II)

Interference species	Tolerance limit, [Interferent] / [Cd(II)]	Recovery %
$\text{HPO}_4^{2-}$ , $\text{NO}_3^-$ , $\text{F}^-$ and $\text{SO}_4^{2-}$	>1500	98.2-102.5
$\text{Mg}^{2+}$ , $\text{K}^+$ and $\text{Na}^+$	1000-1500	97.7-98.9
tartrate and citrate	500-1000	98.5-102.1
$\text{Sr}^{2+}$ , $\text{NO}_3^-$ and $\text{Al}^{3+}$	300-500	97.9-99.4
$\text{CN}^-$ , $\text{I}^-$ and $\text{Bi}^{3+}$	350-750	97.3-101.6
$\text{NO}_2^-$ , $\text{SCN}^-$ and $\text{Cr}^{3+}$	200-350	98.3-102.9
$\text{As}^{3+}$ , $\text{Hg}_2^{2+}$ and $\text{Sn}^{4+}$	100-200	95.5-97.3
$\text{Pb}^{2+}$ , $\text{Fe}^{2+}$ and $\text{Mn}^{2+}$	50-100	96.7-100.9
$^{\text{a}}\text{Ni}^{2+}$ , $^{\text{a}}\text{Fe}^{3+}$ and $^{\text{a}}\text{Co}^{2+}$	20-35 ( $^{\text{a}}250$ -500)	96.8-99.3
$^{\text{b}}\text{Ag}^+$ , $^{\text{b}}\text{Hg}^{2+}$ , $^{\text{b}}\text{Cu}^{2+}$	5-15 ( $^{\text{b}}100$ )	95.1-96.7

<sup>a</sup>Tolerance limits in the presence of 0.2 mL of 0.05 mol L<sup>-1</sup> Na<sub>4</sub>P<sub>2</sub>O<sub>7</sub> and 0.2 mL 0.01 mol L<sup>-1</sup> citric acid as masking agents

<sup>b</sup>Tolerance limits in the presence of 0.2 mL of 0.05 mol L<sup>-1</sup> Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>

**Table 3** Determination of Cd(II) contents of some cosmetic samples including SRMs, and recovery studies of spiked samples

Samples	Sample amounts, mL or g	After wet digestion with HNO <sub>3</sub> /HClO <sub>4</sub> /H <sub>2</sub> O <sub>2</sub> (2:2:1, v/v)								Certified value, mg kg <sup>-1</sup> (n: 5)	The calculated t- and F-values
