Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

www.rsc.org/

Ultrathin 2D Co_3O_4 and $\text{Co}_3\text{V}_2\text{O}_8$ nanosheets have been produced from our modified hydrothermal (MHT) technique. Both the materials have proved to be extraordinary electrode materials for pseudocapacitance. The neat nanosheets of Co_3O_4 and $\text{Co}_3\text{V}_2\text{O}_8$ exhibit record specific capacitance value 1256 F/g and 4194 F/g at 1 A/g current density, respectively.

Supercapacitors with fast charge-discharge property, large cyclic stability, high power density and large coulombic efficiency have drawn attention for practical utility in electrical vehicles, advanced charge storage devices etc.¹ Limitation of supercapacitors lies always with low energy density compared to Li-ion batteries. Energy density can be increased by increasing specific capacitance value (C) and applied cell voltage (V). To increase the applied cell voltage generally solid state asymmetric electrodes are designed which consist of battery-like and capacitor-like electrodes.² Between the electrochemical double layer capacitor and pseudocapacitor, the latter has become more popular for its high specific capacitance value and fast charge-discharge property due to rapid reversible multi-electron relay via Faradic redox reactions.³ For this purpose many redox active materials such as MnO_2 ,⁴ $\text{Ni}(\text{OH})_2/\text{NiO}$,^{3,5} $\text{Co}_3\text{O}_4/\text{Co}(\text{OH})_2$ ^{6,7} etc. have been used. The pseudocapacitor, in most cases, faces major problem as the materials involve only the surface layers again which are often discontinuous and also bear non-participating bulk. Thus utility of the active material in case of pseudocapacitor becomes less effective. Now a days fabrication of electrode for charge storage with mixed oxides has been proved to be promising materials due to their synergistic effect.⁸⁻¹⁵ Among the transition metal oxides researchers are now interested towards vanadium oxide, due to its large number of oxidation state, high abundance, non-toxicity etc.⁹⁻¹⁵ All these effects are supplemented due to the

maximum utilization of active material which increases the quality of the pseudocapacitor. Ultrathin two-dimensional (2D) nanosheets are proved to be very significant in practice due to their remarkable chemical as well as physical properties, such as high molecular thickness, provision of large number of active sites, good structural stability, short diffusion path length, etc.^{4,7,16,17}

By keeping the above considerations and limitations in mind, here in this communication we report the preparation of two different cobalt based nanosheets C_1 and C_2 (Co_3O_4 and $\text{Co}_3\text{V}_2\text{O}_8$, respectively) using our laboratory developed modified hydrothermal technique (MHT)¹⁸ in liquor ammonia solution (supporting information provides discussion). The as-synthesized materials are used as electrochemical pseudocapacitor in a three-electrode system where glassy carbon has been used as the working electrode. The mixed oxide electrode material exhibits very high specific capacitance, high stability and high energy density value. Interestingly, we have obtained thin nanosheets for both Co_3O_4 and $\text{Co}_3\text{V}_2\text{O}_8$ samples from MHT. The crucial stages of the synthetic strategy are temperature and usage of liquor NH_3 as the hydrolyzing agent. There are some reports of $\text{Co}_3\text{V}_2\text{O}_8$ nanostructure preparation but none of them reported sheet like morphology.⁹⁻¹³ Figure S1 demonstrates the schematic presentation of the synthesis of C_2 sample. A homogeneous alkalisation of precursor salt solutions with strong ammonia hydrolyses metal salts under MHT. The formation of ultrathin nanosheets is dominated by self-assembly and oriented attachment mechanism.¹⁹ In the oriented attachment process nanoparticles rotate to optimize the crystallographic orientation at low surface energy. Finally at the interface irreversible attachment occurs with each other through lateral atom-by-atom addition.²⁰ Again, ammonia by its intrinsic driving force, presumably through H-bonding, initiates 2D anisotropic growth of the materials. NH_4^+ from aqueous ammonia has a significant role to modify the surface of the metal oxide nanoparticles. Different binding ability and hydrogen bond formation of ammonium ion with the metal ions (here Co^{2+} and V^{5+}) may be the reason behind the variation in the surface energies of the metal oxide

nanocrystals. During this process, at a particular condition i.e., at low surface energy metal oxide nanoparticles assemble in a symmetric configuration which leads to the formation of nanosheet. Finally, MHT condition dehydrates the product of hydrolysis to oxide.²¹ Other common hydrolyzing agents were unsuccessful in this endeavor to produce sheets.

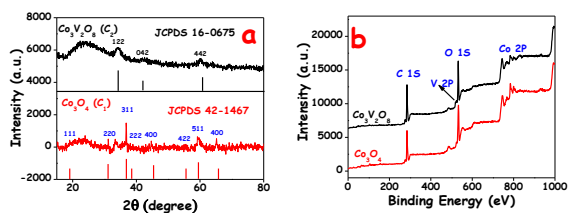

Fig. 1 a) XRD and b) wide range XPS of the C₁ and C₂ samples.

To characterize the as-synthesized nanosheets useful characterization techniques have been used. Figure 1a displays the XRD patterns of the samples C₁ and C₂ which matches well with the reported Co₃O₄ and Co₃V₂O₈ results.^{6,13} Red line (C₁) in Figure 1a indicates the face centered cubic phases of Co₃O₄ (JCPDS 42-1467) with cell constants values, a = b = c = 0.8083 nm where diffraction peaks with their crystal planes are visible.⁶ On the other hand, black line (C₂) confirms the cubic phase of Co₃V₂O₈ (JCPDS 16-0675) with their crystal planes and characteristic diffraction peaks.¹³

Fig. 2 TEM images of a) C₂ and b) C₁ samples, respectively. c) HRTEM image and d) AFM image and thickness profile of C₂ sample.

Wide range XPS of C₁ and C₂ samples (Figure 1b) indicates that C₁ is comprised of Co and O only and that of C₂ is with Co, V and O. Figure S2a also confirms that V is present in C₂ sample. Narrow range XPS of C₁ and C₂ (Figure S2b and c) demonstrates Co 2p, V 2p regions. For sample C₁, the Co 2p_{1/2} and Co 2p_{3/2} are located at 797.5 eV and 781.8 eV, respectively which authenticates that C₁ is Co₃O₄.²² On the other hand for C₂ the Co 2p_{1/2} and Co 2p_{3/2} are positioned at 796.5 eV and 780.7 eV, respectively together with a strong satellite peak, characteristic of Co²⁺, for sample C₂. The V 2p_{1/2} and V 2p_{3/2} positioned at 517.1 eV and 523 eV justify Co²⁺ and V⁵⁺ in C₂ implying it a Co₃V₂O₈.¹⁰ EDS result also confirms that C₂ is composed of Co, V and O (Figure S3). Field emission scanning electron microscopic (FESEM, Figure S4a,b), transmission electron microscopic (TEM, Figure 2a,b), scanning transmission

electron microscopic (STEM, Figure S4c,d) and atomic force microscopic (AFM, Figure S4e,f) analyses clearly reveal the ultrathin morphology for both the as-synthesized Co₃O₄ (C₁) and Co₃V₂O₈ (C₂) samples. Figure 2c shows lattice spacing for C₂ sample, bearing interplaner distance of 0.254 nm for (121) plane and that of C₁ appears at 0.284 nm for (220) plane (Figure S5a), which also validate that C₁ and C₂ are Co₃O₄ and Co₃V₂O₈, respectively. AFM measurement reveals the actual thickness of C₁ and C₂ samples which are 4.5 nm and 3.5 nm as observed from Figure S5b and Figure 2d, respectively. Elemental area mapping from STEM image confirms that C₁ is with Co and O only (Figure S6) and C₂ is composed of Co, V and O (Figure S7). N₂ adsorption-desorption isotherm of C₁ and C₂ samples were analyzed at 77 K in the region of relative pressure 0 to 1 (P/P₀) (figure S8). The BET surface area and pore diameter of the C₁ sample is 70 m²/g and 4.02 nm, respectively and that of C₂ sample is 76 m²/g and 4.1 nm, respectively, i. e., both the materials are mesoporous in nature.

Here we have used both the as-synthesized metal oxides as electrode materials for a pseudocapacitor. Both the samples inherit very high specific capacitance value, moderate rate capability, long range stability, high energy and power density. The total experiment has been carried out in 3M KOH solution. Figure 3a represents the cyclic voltammetry (CV) curve for C₁ and C₂ samples in the potential range -0.2 V to 0.4 V at triangular scan rate of 10 mV/s. In both the cases two pairs of redox peaks appear. The redox peaks indicate the involvement of two quasi-reversible electron transfer redox processes within the applied voltage. The reaction signatures are as follows:^{23,24}

It can be spelt out that, in alkaline medium Co₃V₂O₈ as well as Co₃O₄ react through Co (II) ↔ Co (III) ↔ Co (IV) redox stages. These faradic redox reactions are the reasons behind the mechanism of charge storage by the as-synthesized materials (pseudocapacitive nature).^{23,24} Due to these redox reactions the peak shaped CV curves are produced.^{23,24} This pseudocapacitive nature is very much different from electrical double layer capacitor (EDLC), as EDLC produces rectangular shaped CV curve.²⁴ Figure S9a,b illustrates that with the increase in scan rate the current density for both the samples increases. This is due to the fact that at high scan rate diffusion of OH⁻ ion is high and pronounced. From Figure S9a,b it is also observed that the anodic peaks and the cathodic peaks are not symmetrical. This indicates kinetic irreversibility of the material which occurs owing to the ohmic resistance and polarization during the redox reactions.²³ As per Figure 3b, the nonlinear charge-discharge curve for C₁ and C₂ again approves that, C₁ and C₂ exhibit pseudocapacitance in KOH electrolyte. The as-synthesized ultrathin nanosheets showed specific capacitance value 1256 F/g and 4194 F/g at 1 A/g current density for C₁ and C₂, respectively.

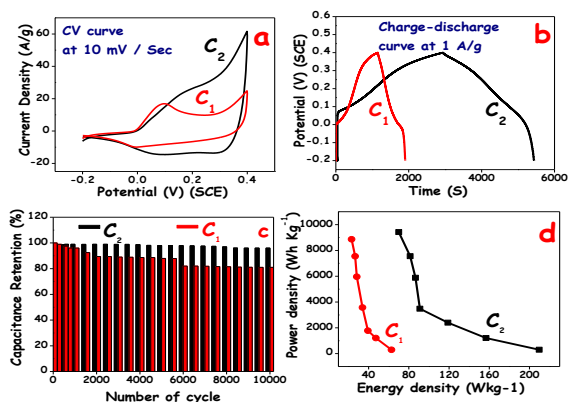

Fig. 3 a) CV curve at 10 mV/S scan rate, b) charge discharge curve at 1 A/g, c) percentage specific capacitance retention after 10000 cycles and d) Ragone plot for C₁ and C₂ sample.

Recently, researchers have tried to develop advanced pseudocapacitor materials with high specific capacitance value from different techniques through synthesis of sheet like materials, doping and also addition of redox active materials with the electrolyte.²⁵⁻²⁸ Here in this case we have obtained an excellent specific capacitance value from our ultrathin 2D Co₃V₂O₈ (C₂) only in aq. KOH electrolyte, without adding any redox active agent. The specific capacitance value of the as-synthesized C₁ is also superior than the recently reported Co₃O₄.^{6,8,22,29} Table S1 represents the specific capacitance of the reported Co₃O₄ and other electrode materials where most of them bear sheet like morphology.

Table S2 contains the specific capacitance values of C₁ and C₂ at different current densities. We have checked the rate up to very high current density (30 A/g) for both the materials. At 30 A/g the specific capacitance values for C₁ and C₂ are 461 and 1400 F/g, respectively, i.e., at this current density the capacitance retention for C₁ is 36.71 % and that of C₂ is 33.34 %. As a pseudocapacitor these rate capability values are not bad at such high current density (here we did not use any carbonaceous material to increase the electrical conductivity^{30,31}). At high current density C₁ shows high rate capability than C₂. This anomaly may be due to the high surface activation of C₁ compared to C₂ at high current density. For pseudocapacitor, redox reactions occur at the electrode-electrolyte interface and electrolyte can diffuse to ~20 nm depth of the active material.³² In our case thickness of both the materials is <5 nm and thus involvement of the whole surface as active material is understandable. Hence, ultrathin flat structures of both the materials make the ion diffusion process fast, extremely facile due to whole body participation of the active material. On the other hand mesoporous nature on the nanosheets increases the wettability of the electrode, and facilitates the fast ion transport which in turn increases the rate capability.³³ Figure S10a,b display the charge-discharge curve of C₁ and C₂ electrode materials at different current densities and Figure 3c demonstrates the stability of C₁ and C₂ at 30 A/g current density after 10000 cycles of charge-discharge. From this graphical presentation it is clear that after 10000 cycles C₁ retains 81% of its specific capacitance and whereas the same in case of C₂ is 96%, i.e. synergistic effect of

cobalt and vanadium oxide in C₂ sample makes it stable electrode for a pseudocapacitor. This cyclic durability of the materials is essential for practical purpose. The kinetic irreversibility of the materials is further substantiated from the measured coulombic efficiency (η). Coulombic efficiency is governed by the quantitative charging time (t_c) and discharging time (t_d). The smaller the Δt , lower the kinetic irreversibility and higher the accessibility of the surface for the OH⁻ ion.²⁴ In our case, for C₂, η value increases from 88% to ~100% when current density increases from 1 A/g to 20 A/g, and for C₁, η values increase from 67% to ~100% when current density increases from 1 A/g to 30 A/g. Increase in η to such a large extent illustrates the structural activation and, high reversibility with the progress of charge discharge cycle. Structural activation during charge-discharge cycle in such high current density provides much more involvement of the interfacial ions which facilitates the mass transfer.³⁴ It is observed that at 1 A/g, η for C₂ is 88% and that of C₁ is 67%, which signify that active surface molecules in C₂ are higher than the C₁. This is also corroborated from the observed higher roughness of C₂ (Figure S11 and Figure S8). Generally it is observed that for an increase in charge-discharge cycle the coulombic efficiency gradually decreases after certain time due to the structural changes. For C₁ nanosheet, coulombic efficiency gradually decreases only after 800 cycles and becomes fixed at 81% through 7000 cycles. After that η values decrease to 76% and becomes fixed up to 10000 cycles. But for C₂, the coulombic efficiency remains almost 100% till 8000 cycles. After 8000 cycles coulombic efficiency decreases to 94% and becomes fixed up to 10000 cycles. This discrepancy occurs for C₁ due to the ruptured structure during the charge-discharge cycle at higher current density but for C₂, the structure remains intact indicating the inherited robustness of the nanosheet due to the presence of vanadium oxide in Co₃V₂O₈ matrix. Presence of vanadium oxide provides a structural support to the Co₂V₂O₈ matrix.¹⁴ TEM images of C₁ and C₂ after 10000 cycles (Figure S12) also confirm the interpretation in the discussion. From the above discussion it is evident that the superior electrochemical activity of the Co₃V₂O₈ is due to the synergistic effect of binary metal oxide (Co and V).^{14,15} In recent days, researchers use current collectors like Ni foam^{6,8,22,29} or carbon fiber²⁷ having large surface area to get high specific capacitance value for supercapacitor material. In our case we used glassy carbon as the working electrode whose surface area is very small than the carbon fiber or Ni foam, yet the materials showed specific capacitance value superior to most of the reported direct and indirect nanostructured electrodes.^{6,8,22,29} Figure 3d demonstrates the Ragone plot (energy density vs. power density). Here, we can see that power density of C₁ sample is comparable to C₂ but energy density is quite low than C₂. Here in our case C₂ shows energy density 209.66 Wh kg⁻¹ and power density 302.3 W kg⁻¹ at 1 A/g current density, again at 30 A/g energy density is 70 Wh kg⁻¹ and power density is 9420.56 W kg⁻¹. On the other hand, C₁ shows energy densities 62.8 and 23.05 Wh kg⁻¹ at power densities 300.53 and 8865.38 W kg⁻¹ at 1 A/g and 30 A/g current density, respectively. Interestingly,

for C_2 energy density is very much competitive with the Li-ion batteries and much higher than the reported supercapacitors (Table S3 demonstrates the energy density of the reported pseudocapacitors).^{2,34,35}

Fig. 4 (a) CV curve at 10 mV/S scan rate and (b) charge-discharge curve at 1 A/g current density for $Co_3V_2O_8//AC$ and $Co_3O_4//AC$, respectively.

To support the electrochemical superiority of the as-synthesized nanosheets, electrochemical impedance spectroscopic (EIS) measurements (Figure S13) have also been done which is discussed briefly in the supporting information. In order to investigate the practical utilization of the as-synthesized nanosheets (Co_3O_4 and $Co_3V_2O_8$), asymmetric two electrode cell has been developed where Co_3O_4 and $Co_3V_2O_8$ were used as the positive electrode and activated carbon (AC) was used as the negative electrode. Fabrication of the asymmetric cell for both samples has been discussed in the supporting information. Figure 4 illustrates the CV curves and charge discharge curve for both the two electrode cells, $Co_3O_4//AC$ and $Co_3V_2O_8//AC$. Redox peaks in the CV curves for both samples indicate the pseudocapacitive nature of the asymmetric supercapacitor. Charge-discharge plot, stability with cycles, Nyquist plot and Ragone plot have been discussed in the supporting information for both the assembled cells. Specific capacitance value of $Co_3O_4//AC$ and $Co_3V_2O_8//AC$ assembled cells are 121 F/g and 303 F/g, respectively at 1 A/g current density. Due to the superior specific capacitance values and high voltage window (1.6 V), energy density values of the asymmetric supercapacitors are also very high (43.09 Wh kg^{-1} for $Co_3O_4//AC$ and 107.95 Wh kg^{-1} for $Co_3V_2O_8//AC$).

In summary, we, for the first time, have described the importance of strong ammonia mediated hydrolysis under MHT for the synthesis of two ultrathin 2D cobalt oxide nanosheets with superior electrochemical activity. The as-synthesized Co_3O_4 with its 2D ultrathin nanosheet structure has proved to be a very efficient pseudocapacitor material. Then judicious insertion of robust vanadium oxide, considering its multiple oxidation states, into Co_3O_4 matrix makes it an extraordinary pseudocapacitor, $Co_3V_2O_8$. Especially, the as-synthesized $Co_3V_2O_8$ nanosheet shows high specific capacitance value, excellent structural stability, and electrochemical stability after extended charge-discharge cycles. Above all, energy density of $Co_3V_2O_8$ is very high and remarkably competitive to the Li-ion battery and other reported super capacitors.

The authors are thankful to DST, India and CSIR, New Delhi for financial assistance, Prof. Kumar Biradha, Department of Chemistry, IIT Kharagpur for BET measurement and IIT Kharagpur for instrumental support.
