2 **Abstract**

3 Three-dimensionally ordered macroporous (3DOM) SiO<sub>2</sub> was synthesized by  
4 colloidal crystal template (CCT) method, and 3DOM SiO<sub>2</sub>-supported transition metal  
5 oxides catalysts were prepared by facile incipient-wetness impregnation method. The  
6 as-prepared catalysts show well-defined three-dimensionally ordered macroporous  
7 structures. The transition metal oxides formed different sizes of nanoparticles and  
8 loaded on the 3DOM SiO<sub>2</sub>. The as-prepared catalysts show high catalytic activities for  
9 soot combustion. Among the studied catalysts, 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst (molar  
10 ratio of Mn to Si is 1:4) shows the highest catalytic activity among the studied  
11 catalysts, e.g. T<sub>10</sub>, T<sub>50</sub> and T<sub>90</sub> are 297, 355 and 393 °C, respectively, and S<sup>m</sup><sub>CO2</sub> is  
12 95.5%. The catalytic performance of 3DOM SiO<sub>2</sub>-supported transition metal oxide  
13 catalysts are mainly controlled by three factors: the macroporous effects of 3DOM  
14 structure, the redox properties of transition metal oxides and the sizes of transition  
15 metal oxides NPs. 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts are  
16 promising for practical applications in soot combustion owing to high activity and low  
17 cost.

## 1 Introduction

3 Nowadays, toxicological and epidemiological studies indicate that soot particles of  
4 diesel exhaust are threatening the environment and people's health.<sup>1</sup> A great number  
5 of illness, which include irritation of the eyes, throat vomiting, light-headedness,  
6 headache, heartburn, bronchitis, lung cancer or even premature death and so on, have  
7 been triggered by soot particles.<sup>2</sup> In addition, soot particles are also a main source of  
8 urban atmospheric particulate matters (PM<sub>2.5</sub>).<sup>3</sup> A lot of previous works demonstrated  
9 that the exhaust of diesel engine is one of the largest contributors to soot particles in  
10 the most large and medium-sized cities. Therefore, elimination of diesel engine  
11 exhaust (especially for soot particles) is urgent for development of society and  
12 economy.<sup>4</sup> Indeed, great efforts have been made to reduce the soot particles to meet  
13 the stringent environmental regulations and protect human health.<sup>5</sup> Researches  
14 indicate that the after-treatment of diesel exhaust is one of the most perspective  
15 techniques, and the catalyst is one of important controlling factors for soot  
16 elimination.<sup>6,7</sup> Therefore, the development of novel catalyst is one of the most  
17 important tasks for elimination of soot particles.

18 A number of catalysts have been studied for soot combustion at low temperatures,  
19 including noble metals<sup>8</sup>, perovskite-type oxides<sup>9</sup>, CeO<sub>2</sub>-based oxides<sup>10,11</sup>, etc. Since it  
20 is a gas-solid-solid reaction for catalytic soot combustion, it is affected by two factors,  
21 the contact efficiency between soot and catalyst, and the intrinsic activity of catalyst.  
22 Because traditional catalysts show smaller pore sizes (<10 nm) than soot particles

1 (>20 nm), soot particles are difficult to enter the inner pores of these catalysts.<sup>12</sup>  
2 Recently, three-dimensionally ordered macroporous materials with uniform pore size  
3 (>50 nm) and well-defined structure have been applied in the field of heterogeneous  
4 catalysis.<sup>13-15</sup> Due to ordered macroporous structures, soot particles could easily enter  
5 their inner pores, and thus they flexibly access the active sites. A series of 3DOM  
6 metal mixed oxides, including  $\text{La}_{1-x}\text{K}_x\text{CoO}_3$ <sup>16</sup> and  $\text{Ce}_{1-x}\text{Zr}_x\text{O}_2$ <sup>17</sup> and so on, have been  
7 prepared in our group, and they all show better catalytic performances than  
8 corresponding nanoparticle catalysts for soot oxidation. The intrinsic activity of  
9 catalyst is another factor for enhancing catalytic activity after resolving the contact  
10 efficiency. To further improve the intrinsic activity of catalysts, our group have  
11 prepared a series of 3DOM oxides-supported Au or/and Pt catalysts.<sup>18-22</sup> Those  
12 catalysts all exhibit super high catalytic activities for soot combustion. However, due  
13 to the limited resources, noble metal catalysts are very expensive than metal oxide  
14 catalysts, which restricts the extensive application of noble metal catalysts.

15 In the past decades, low-cost catalysts, including single metal oxides, mixed metal  
16 oxides, perovskites, spinels, alkali earth metals and alkali metals, etc. showed high  
17 catalytic activity for soot combustion.<sup>23-26</sup> As always, nano-catalysts have been used in  
18 the field of catalysis and they show excellent catalytic activities in many reactions  
19 especially for oxidation reactions.<sup>27-29</sup> Therefore, the nano-catalysts are also expected  
20 to exhibit high catalytic activities for soot combustion.<sup>31,32</sup> However, design and  
21 preparation of low cost catalysts to combine nano-effect and macroporous effect are  
22 promising for increasing of catalytic activity for soot combustion and practical

1 application. Researchers have demonstrated that transition metal oxides with changing  
2 valence states display excellent redox properties when they are applied in the  
3 oxidation reactions.<sup>33-36</sup> Based on the above reasons, transition metal oxides  
4 nanoparticles (NPs) supported on 3DOM SiO<sub>2</sub>, are expected to enhance catalytic  
5 performance for soot combustion by making the best of nano-effect and macroporous  
6 effect in 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts.

7 In this paper, 3DOM SiO<sub>2</sub> support was synthesized by colloidal crystal template  
8 (CCT) method. 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts were  
9 prepared by incipient wetness impregnation method. The physical and chemical  
10 properties of as-prepared catalysts were characterized by means of X-ray  
11 diffraction (XRD), scanning electron microscopy (SEM), transmission electron  
12 microscopy (TEM), temperature-programmed reduction with H<sub>2</sub> (H<sub>2</sub>-TPR)  
13 measurements, UV-Vis diffuse reflectance spectra (DRS) and X-ray photoelectron  
14 spectra (XPS) etc. The catalytic performances of as-prepared catalysts were  
15 evaluated for soot combustion, and the effects of different transition metal oxide on  
16 the catalytic activities for soot combustion were investigated.

## 17 2 Experimental

### 18 2.1 Catalysts preparation

#### 19 2.1.1 Synthesis of highly well-defined PMMA microspheres

20 The synthesis of monodispersed PMMA (polymethyl methacrylate) microsphere  
21 and the assembly template are similar to that described previously<sup>22</sup>. Detailed  
22 procedures are described in supporting information.

### 1 2.1.2 Synthesis of 3DOM SiO<sub>2</sub>

2 3DOM SiO<sub>2</sub> was synthesized by colloidal crystal template (CCT) method with  
3 PMMA arrays as template and using tetraethyl orthosilicate (TEOS) as precursors. In  
4 a typical procedure, 4.6 g TEOS was dissolved into the mixture of water (2.5 mL),  
5 alcohol (5 mL) and HCl aqueous solution (2mol/L, 2.5 mL). After that, the  
6 hydrolyzation was proceeded in a water bath at 35 °C for 4 h. Then, 3g PMMA arrays  
7 were added into the above solution for impregnation. After complete impregnation,  
8 the PMMA arrays with the precursor solution were separated by vacuum filter and  
9 dried at 30 °C for 24 h. The dried samples were calcined to remove the CCT in a tube  
10 furnace with an air flow (80 mL min<sup>-1</sup>). The temperature-rising rate was 1 °C min<sup>-1</sup>  
11 from room temperature to 600 °C, and the temperature of calcination at 600 °C was  
12 kept for 4 h, and then 3DOM SiO<sub>2</sub> supports were obtained.

### 13 2.1.3 Synthesis of 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts

14 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts were prepared by  
15 incipient-wetness impregnation method. In a typical procedure, a certain amount of  
16 transition metal nitrates (50 wt% Mn(NO<sub>3</sub>)<sub>2</sub> aqueous solution, Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O,  
17 Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O) were dissolved into deionized  
18 water, and then the above aqueous solution was added into 3DOM SiO<sub>2</sub>. After that,  
19 the impregnated sample was dealt with ultrasonic for 10 min and dried at 80 °C for 24  
20 h. Then, the sample was calcined at 550 °C for 4 h in tube furnace and 3DOM  
21 SiO<sub>2</sub>-supported transition metal oxide catalysts were obtained. The stoichiometric  
22 ratios of raw materials for 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts are

1 listed in the Table 1. In addition, different loading amounts of manganese nitrate on  
2 3DOM SiO<sub>2</sub> were also prepared and the corresponding dosages of raw materials are  
3 also listed in the Table 1.

## 4 2.2 Physical and chemical characterization

5 XRD patterns were measured on a powder X-ray diffractometer (Bruker D8  
6 Advance) using CuK $\alpha$  ( $\lambda=0.15406$  nm) radiation with a Nickel filter operating with  
7 voltage and current of 40 kV and 40 mA in the  $2\theta$  range of 10-90° at a scanning step  
8 of 0.02°. The patterns were compared with JCPDS reference data for phase  
9 identification. The surface morphology of the catalyst was observed by field emission  
10 scanning electron microscopy (FESEM) on a Quanta 200F instruments using  
11 accelerating voltages of 5 kV. SEM samples were dusted on conducting resin and  
12 coated with 10 nm Au prior to measurement. The TEM images were obtained using a  
13 JEOL JEM-2100 transmission electron microscope. A typical TEM sample was  
14 prepared by adding several droplets of a nanoparticles/ethanol mixture onto a  
15 carbon-coated copper grid. Nitrogen adsorption/desorption isotherms at -196 °C were  
16 recorded using a Micromeritics TriStar II 3020 porosimetry analyzer. The samples  
17 were degassed at 300 °C for 4 h prior to the measurements.

18 H<sub>2</sub>-TPR was performed using a Quantachrome Autosorb-iQ, USA. A sample of 100  
19 mg was loaded into a U-shaped quartz reactor and pre-treated in Ar at 300 °C for 1 h.  
20 After cooling to room temperature, the flow gas was switched to 10-vol% H<sub>2</sub>/Ar, and  
21 the catalyst was heated to 900 °C at a rate of 10 °C min<sup>-1</sup>. The flow rate of 10-vol%  
22 H<sub>2</sub>/Ar is 50 mL min<sup>-1</sup>. The consumption of hydrogen was recorded by thermal

1 conductivity detector (TCD). Calibration of the instrument was carried out with CuO  
2 of known amount. X-ray photoelectron spectra (XPS) were recorded on a  
3 Perkin-Elmer PHI-1600 ESCA spectrometer using Mg K $\alpha$  X-ray source. The binding  
4 energies were calibrated using C1s peak of contaminant carbon (BE = 284.6 eV) as an  
5 internal standard.

### 6 2.3 Activity measurements

7 The catalytic performances of all catalysts were evaluated with a  
8 temperature-programmed oxidation reaction (TPO) on a fixed-bed tubular quartz  
9 reactor ( $\Phi$ = 8 mm), and each TPO run from 150 to 650 °C at a 2 °C min<sup>-1</sup> rate. The  
10 model soot was Printex-U particulates (diameter 25 nm, purchased from Degussa).  
11 The catalyst (100 mg) and soot (10 mg) were mixed at a weight ratio of 10:1 with a  
12 spatula in order to reproduce the loose contact mode. Reactant gases (50 mL min<sup>-1</sup>)  
13 contain 10% O<sub>2</sub> and 0.2% NO balanced with Ar. The outlet gas compositions were  
14 analyzed with an on-line gas chromatograph (GC, Sp-3420, Beijing) by using FID  
15 detectors. Before entering the FID detector, CO and CO<sub>2</sub> were fully converted to CH<sub>4</sub>  
16 by a convertor with Ni catalyst at 380 °C. The catalytic activity was evaluated by the  
17 values of T<sub>10</sub>, T<sub>50</sub> and T<sub>90</sub>, which were defined as the temperatures at 10%, 50% and  
18 90% of soot conversion, respectively. The selectivity to CO<sub>2</sub> formation (S<sub>CO<sub>2</sub></sub>) was  
19 defined as that the CO<sub>2</sub> outlet concentration (C<sub>CO<sub>2</sub></sub>) divided by the sum of the CO<sub>2</sub> and  
20 CO outlet concentration, i.e.,  $S_{CO_2} = C_{CO_2} / (C_{CO} + C_{CO_2})$ . S<sup>m</sup><sub>CO<sub>2</sub></sub> was denoted as S<sub>CO<sub>2</sub></sub> at  
21 the maximum temperature corresponding to the soot-burnt rate was the highest. In all  
22 TPO experiments, the reaction was not finished until the soot was completely burnt

1 off.

## 2 3 Results and discussion

### 3 3.1 Catalyst characterization

#### 4 *3.1.1 The results of XRD*

5 XRD patterns of 3DOM SiO<sub>2</sub>-supported transition metal catalysts are shown in  
6 Figure 1. As shown in Figures 1a-g, different transition metal catalysts exhibit various  
7 diffraction peaks. For the pure SiO<sub>2</sub> (Figure 1a), a broad peak at 2θ of 23.5° can be  
8 observed, which is typical peak of amorphous silica.<sup>37</sup> An overview of the XRD  
9 patterns of as-prepared 3DOM transition metal catalysts in Figures 1b-f indicates that  
10 transition metal oxides formed after the process of calcination. The detailed  
11 explanations about 3DOM SiO<sub>2</sub>-supported transition metal catalysts are shown in the  
12 Supplementary Information. In addition, from the Figures 1b-f, it can be seen that the  
13 peak of amorphous silica disappeared when transition metal oxides were supported on  
14 the surface of 3DOM SiO<sub>2</sub>. The XRD patterns of 3DOM SiO<sub>2</sub>-supported MnO<sub>x</sub>  
15 catalysts with different MnO<sub>x</sub> loading amounts are shown in Figures 1g-j. With the  
16 increasing of MnO<sub>x</sub> loading amount, the intensity of diffraction peaks of amorphous  
17 SiO<sub>2</sub> becomes weaken and some feature peaks of manganese oxide appear and their  
18 intensities enhance. As shown in Figures 1i-j, the diffraction peaks of SiO<sub>2</sub> almost  
19 disappear when the loading amount of MnO<sub>x</sub> is over a certain value (molar ratio of  
20 Mn to Si is over 1:4). It is attributed to MnO<sub>x</sub> coated on the surface of 3DOM SiO<sub>2</sub>.

#### 21 *3.1.2 The results of SEM*

22 Figure 2 shows the SEM images of 3DOM SiO<sub>2</sub>-supported transition metal

1 catalysts with loading of different transition metals. The SEM images show that the  
2 macropores with average diameter of ca.  $310\pm 20$  nm are interconnected through open  
3 windows, ca. 90-140 nm in diameter, and the wall thicknesses are ca. 30-50 nm<sup>17</sup>. As  
4 shown in the Figures 2a-f, it can be seen that the macropores have uniform pore sizes,  
5 windows and wall thicknesses, and those macropores are highly periodically arrayed  
6 and interconnected through small windows. These SEM images clearly demonstrate  
7 that all 3DOM samples have long range ordered macroporous structure. As shown in  
8 the inserted SEM images, some dark dots in macropores were visible clearly. The  
9 SEM images suggest that the process of supporting transition metal oxides on 3DOM  
10 SiO<sub>2</sub> has no influence on 3DOM structure.

11 Figure 3 shows the SEM images of 3DOM SiO<sub>2</sub>-supported MnO<sub>x</sub> catalysts with  
12 different MnO<sub>x</sub> loading amounts. From the Figure 3 and Figure 2b, it can be seen that  
13 3DOM structure is clearly observed when the ratio of Mn to Si is lower than 1:4  
14 (Figures 3a,b and Figure 2b), while 3DOM structure has a little destruction when the  
15 molar ratio of Mn to Si is over 1:4 (Figures 3c,d). The reason for the result may be  
16 that the excess MnO<sub>x</sub> agglomerated and formed big particles. 3DOM structure of SiO<sub>2</sub>  
17 is affected by the big particles. From the all SEM images with different MnO<sub>x</sub>  
18 loading amounts, it can be concluded that 3DOM structure can be maintain when  
19 MnO<sub>x</sub> loading amount is lower than a certain constant (molar ratio of Mn to Si is 1:4).

### 20 *3.1.3 The results of TEM*

21 TEM images of 3DOM SiO<sub>2</sub>-supported transition metal catalysts with loadings of  
22 different transition metals are shown in Figure 4. From the Figure 4a, it can be seen

1 that 3DOM SiO<sub>2</sub> with over-lapped pores can be clearly observed by TEM image. No  
2 granular or spherical SiO<sub>2</sub> are observed on the surface of 3DOM SiO<sub>2</sub>. Combined with  
3 XRD result of SiO<sub>2</sub> (Figure 1a), it indicates that the framework of 3DOM SiO<sub>2</sub> was  
4 accumulated by amorphous SiO<sub>2</sub>. As shown in Figures 3b, c, the surface of 3DOM  
5 SiO<sub>2</sub> is successfully decorated with well-dispersed MnO<sub>x</sub> and Fe<sub>2</sub>O<sub>3</sub> nanoparticles  
6 (NPs), and no larger agglomerated particles is observed. The MnO<sub>x</sub> NPs with particle  
7 size of 10-30 nm and Fe<sub>2</sub>O<sub>3</sub> NPs with particle size of 4-13 nm are adhered on the  
8 walls of 3DOM SiO<sub>2</sub>. The average MnO<sub>x</sub> and Fe<sub>2</sub>O<sub>3</sub> NPs sizes are estimated to be  
9 23.5±3.6 and 8.6±2.4 nm for 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> catalysts,  
10 respectively. And the particle size of Co<sub>3</sub>O<sub>4</sub> NPs on 3DOM Co<sub>3</sub>O<sub>4</sub>/SiO<sub>2</sub>, which the  
11 average value is about 60 nm in Figure 4d, is much bigger than 3DOM MnO<sub>x</sub>/SiO<sub>2</sub>  
12 catalysts. The TEM image (Figure 4e) of NiO/SiO<sub>2</sub> catalyst shows that NiO NPs are  
13 supported on the surface of 3DOM SiO<sub>2</sub>, while the particle size of NiO NPs is located  
14 in the range of 20-50 nm. This large particle size is disadvantageous to the catalytic  
15 activity of catalyst. TEM image of CuO/SiO<sub>2</sub> (Figure 4e) shows that the part of dark  
16 place is bulk CuO, indicating that bulk CuO formed in the process of calcination. The  
17 SEM (Figure 2) and TEM (Figure 4) images of 3DOM SiO<sub>2</sub>-supported transition  
18 metal catalysts suggest that 3DOM structure of SiO<sub>2</sub> well maintains and the transition  
19 metal oxides exhibit different particle sizes with different transition metal elements.

20 Figure 5 shows the TEM images of 3DOM SiO<sub>2</sub>-supported MnO<sub>x</sub> catalysts with  
21 different MnO<sub>x</sub> loading amounts. From Figures 5a,b and Figure 4b, it can be seen that  
22 the surface of 3DOM SiO<sub>2</sub> is successfully decorated with well-dispersed MnO<sub>x</sub> NPs

1 and no larger agglomerated particles is observed when molar ratio of Mn to Si is less  
2 than 1:4. The  $\text{MnO}_x$  NPs with particle size of 10-30 nm are adhered on the walls of  
3 3DOM  $\text{SiO}_2$ . However, the particle size of  $\text{MnO}_x$  NPs increases with increasing of  
4  $\text{MnO}_x$  loading amount. The particle sizes of  $\text{MnO}_x$  particles are about 50 nm and 150  
5 nm for  $\text{MnO}_x/\text{SiO}_2$  when molar ratios of Mn to Si are 1:3 and 1:2. It is attributed to  
6 that the concentration of impregnation liquid ( $\text{Mn}(\text{NO}_3)_2$  aqueous solution) become  
7 higher and higher with the increasing of molar ratio of Mn to Si. As shown in the  
8 Figure 5d, most of  $\text{MnO}_x$  particles are supported on outside surface of 3DOM  $\text{SiO}_2$   
9 and no small  $\text{MnO}_x$  particles can be observed on the inner surface of 3DOM  $\text{SiO}_2$ .  
10 This agglomeration of active component of  $\text{MnO}_x/\text{SiO}_2$  catalyst may lead to low  
11 catalytic activity for soot combustion when molar ratio of Mn to Si is 1:2.

### 12 *3.1.4 The results of BET*

13 Nitrogen adsorption-desorption isotherms for 3DOM  $\text{SiO}_2$ -supported transition  
14 metal catalysts were tested and the results are shown in Figure 6. The as-prepared  
15 catalysts exhibit similar adsorption-desorption isotherm shapes. However, their  
16 hysteric loops are different when different transition metals support on 3DOM  $\text{SiO}_2$ .  
17 As shown in Figure 6a and b, 3DOM  $\text{SiO}_2$  and 3DOM  $\text{SiO}_2$ -supported  $\text{MnO}_x$   
18 catalyst show obvious hysteric loops, while the others exhibit small hysteric loops.  
19 The values of surface area, total pore volume and pore size are listed in the Table 2.  
20 3DOM  $\text{SiO}_2$  shows the highest surface area among the as-prepared 3DOM catalysts  
21 and its value is  $270.1 \text{ m}^2/\text{g}$ . The scraggly surface of 3DOM  $\text{SiO}_2$  may contribute to  
22 enhancing the surface area owing to no nanoparticles on the surface. In addition,

1 3DOM SiO<sub>2</sub> shows the lowest pore size among the as-prepared catalysts. The surface  
2 area obviously decreased when transition metals supported on 3DOM SiO<sub>2</sub>. As shown  
3 in the Table 2, the order of surface area value for as-prepared catalysts is as follows:  
4 Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> > MnO<sub>x</sub>/SiO<sub>2</sub> > NiO/SiO<sub>2</sub> > Co<sub>3</sub>O<sub>4</sub>/SiO<sub>2</sub> > CuO/SiO<sub>2</sub>. Combined with the  
5 TEM images in Figure 4, the reason for this order can be explained by the size of  
6 transition metals nanoparticles. In other words, small nanoparticles will contribute to  
7 enhancing the surface area owing to high surface area of small NPs. The total pore  
8 volume and pore size of as-prepared catalysts are different with the different  
9 transition metals. 3DOM SiO<sub>2</sub> shows the highest total pore volume and pore size  
10 among the as-prepared catalysts. From the results of SEM and TEM, it can be seen  
11 that the pore sizes of as-prepared catalysts are more than 300 nm. However, as  
12 shown in the Table 2, the pore sizes of as-prepared catalysts are less than 10 nm. The  
13 reason for this phenomenon is that the value of pore size (based on BET results) is  
14 calculated by BJH desorption average pore diameter. This calculation method does  
15 not contain the macropores. Therefore, the pore sizes (based on BET results) of  
16 as-prepared catalysts are less than 10 nm.

### 17 *3.1.5 The results of UV-Vis diffuse reflectance spectra*

18 The UV-Vis DRS of 3DOM SiO<sub>2</sub>-supported transition metal catalysts were  
19 obtained at room temperature in the range of 200-800 nm. From the Figure 7a, it can  
20 be seen that pure 3DOM SiO<sub>2</sub> has almost no absorption in the ultraviolet and visible  
21 region.<sup>38</sup> As shown in Figure 7b and 8g-j, the relative UV-Vis absorption spectrum of  
22 MnO<sub>x</sub>/SiO<sub>2</sub> indicated the multivalent oxidation states of Mn. Combined with the XPS

1 results, the peaks in the range of 200-350 nm range could be reasonably assigned to  
2  $O^{2-} \rightarrow Mn^{3+}$  charge transfer transitions in the  $MnO_x$ . While the broad peak at 450 nm  
3 was ascribed to the d-d electron transitions of  $Mn^{3+}$  and  $Mn^{4+}$ .<sup>39</sup> From Figure 7c, it  
4 can be seen that the absorption of  $Fe_2O_3/SiO_2$  was rapidly faded when wavelengths is  
5 longer than 560 nm. The broad absorption from 300 to 560 nm corresponds to the  
6  ${}^6A_1 + {}^6A_1 \rightarrow {}^4T_1({}^4G) + {}^4T_1({}^4G)$  excitation of an  $Fe^{3+}-Fe^{3+}$  pair. The absorption at 200 -300  
7 nm is ascribed to the ligand to metal charge transfer transitions and partly contributed  
8 from the  $Fe^{3+}$  ligand field transitions  ${}^6A_1 \rightarrow {}^4T_1({}^4P)$ .<sup>40</sup> As shown in Figure 7d, the  
9 UV-Vis spectra exhibited three different absorbance edges at 200-300, 400-600 and  
10 700-800 nm for  $Co_3O_4/SiO_2$ . The bands ( $\lambda < 500$  nm) can be assigned to the  $O^{2-} \rightarrow$   
11  $Co^{2+}$  charge transfer process, while the band ( $\lambda > 700$  nm) was due to the  $O^{2-} \rightarrow Co^{3+}$   
12 charge transfer.<sup>41</sup> The UV-Vis DRS of  $NiO/SiO_2$  is reported in Figure 7e. The  
13 spectrum of  $NiO/SiO_2$  shows a strong absorption in the UV region, similar to an  
14 absorption plateau with two predominant components at 240 and 300 nm, in  
15 agreement with literature data.<sup>42</sup> The absorption spectrum of  $CuO/SiO_2$  (Figure 7f)  
16 revealed several absorption bands. The band appeared in the 220-360 nm spectral  
17 range can be assigned to the charge transfer transition of the ligand  $O^{2-}$  to isolated  
18 metal center  $Cu^{2+}$  and the d-d transition in  $CuO$  particles. The signal appeared  
19 between 650-800 nm could be ascribed to the  $2E_g \rightarrow 2T_{2g}$  spin-allowed transitions of  
20  $Cu^{2+}$  in the distorted octahedral symmetry.<sup>43</sup>

### 21 3.1.6 The results of $H_2$ -TPR

22 It is well known that soot catalytic combustion is a complicated gas-solid

1 (soot)-solid (catalyst) three-phase reaction. The intrinsic redox properties of catalysts  
2 play a key role in the combustion of soot. In this work, the redox properties of  
3 catalysts were characterized by H<sub>2</sub>-TPR measurements and the results are shown in  
4 the Figure 8. As shown in Figures 8a-f, the peak positions and types of 3DOM  
5 SiO<sub>2</sub>-supported transition metal catalysts vary with different kinds of transition metal.  
6 From the H<sub>2</sub>-TPR profile of 3DOM SiO<sub>2</sub> (Figure 8a), it can be seen that no reduction  
7 peak is observed, indicating that 3DOM SiO<sub>2</sub> exhibits none redox property. Figure 8b  
8 shows the H<sub>2</sub>-TPR profile of MnO<sub>x</sub>/SiO<sub>2</sub>, two main reduction peaks with peak  
9 temperatures at 320 and 416 °C can be observed. Assuming that MnO is the final state  
10 in the reduction of Mn species.<sup>44</sup> The peak at 230 -350 °C could be assigned to the  
11 reduction of MnO<sub>2</sub>/Mn<sub>2</sub>O<sub>3</sub> to Mn<sub>3</sub>O<sub>4</sub>, and the peak at 350-500 °C may be assigned to  
12 the reduction of Mn<sub>3</sub>O<sub>4</sub> to MnO. The results indicate that substantial amount of Mn<sup>4+</sup>  
13 and Mn<sup>3+</sup> in MnO<sub>x</sub>/SiO<sub>2</sub> catalyst can be reduced to Mn<sup>2+</sup> below 500 °C, which is  
14 consistent with the previous reports.<sup>45</sup> Figure 8c depicts the H<sub>2</sub>-TPR profile of  
15 Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, two main peaks, whose peak temperatures are located at 351 and 523 °C,  
16 are characteristics of two reduction steps. The first peak may be assigned to the  
17 reduction of Fe<sub>2</sub>O<sub>3</sub> to Fe<sub>3</sub>O<sub>4</sub>, whereas the second may be attributed to the transition  
18 from Fe<sub>3</sub>O<sub>4</sub> to FeO. Besides the above two main peaks, a weak reduction peak located  
19 at 600 °C can be assigned to the reduction of Fe<sub>3</sub>O<sub>4</sub> to to FeO in the inner Fe<sub>2</sub>O<sub>3</sub>  
20 nanoparticles. Due to small particle sizes and high dispersion of Fe<sub>2</sub>O<sub>3</sub> NPs, the  
21 reduction temperatures are lower than previously reported works. Previous studies  
22 found that the reduction behavior of Co<sub>3</sub>O<sub>4</sub> is highly dependent on the dispersion state

1 of cobalt. Large particles of  $\text{Co}_3\text{O}_4$  were usually reduced to metallic cobalt by a single  
2 step while nanoparticles often went through a two-step process.<sup>46</sup> As shown in the  
3 Figure 8d, two reduction peaks, of which a minor reduction peak at 329 °C and main  
4 reduction peak at 376 °C, are observed for  $\text{Co}_3\text{O}_4/\text{SiO}_2$  catalyst owing to  $\text{Co}_3\text{O}_4$  NPs  
5 with particle size of 60 nm. The two overlapped reduction peaks are corresponded to  
6 the reduction of  $\text{Co}_3\text{O}_4 \rightarrow \text{CoO} \rightarrow \text{Co}$ .<sup>47</sup> Figure 8e shows the  $\text{H}_2$ -TPR profiles of  
7  $\text{NiO}/\text{SiO}_2$  catalyst. Two overlapped reduction peaks with two peak maxima at 350 °C  
8 and 415 °C are obtained, which are consistent with the reduction of two types of  
9  $\text{Ni}^{2+}/\text{Ni}^{3+}$  species to metallic nickel.<sup>48,49</sup> The  $\text{H}_2$ -TPR profile of  $\text{CuO}/\text{SiO}_2$  is shown in  
10 Figure 8f. The minor shoulder reduction peak at 222 °C is assigned to reduction of  
11 dispersed copper oxide, while the main reduction peak at 281 °C is corresponded to  
12 reduction of  $\text{CuO}$ .<sup>42,50</sup> The different reduction peaks of 3DOM  $\text{SiO}_2$ -supported  
13 transition metal catalysts indicate that those catalysts may exhibit various catalytic  
14 activities for soot combustion. Figures 8g-j display the  $\text{H}_2$ -TPR profiles of 3DOM  
15  $\text{MnO}_x/\text{SiO}_2$  catalysts with different  $\text{MnO}_x$  loading amounts. Two main reduction  
16 peaks can be obtained in Figures 8g-j. The peak temperatures increase with the  
17 increasing of  $\text{MnO}_x$  loadings. The first and second reduction peak temperatures  
18 increase from 300 to 336 °C and from 417 to 456 °C, respectively, for the sample with  
19 molar ratio of Mn to Si from 1:16 to 1:2. The possible reason for this result is that  
20 particle size of  $\text{MnO}_x$  increases with the increasing of  $\text{MnO}_x$  loadings (Figure 5). In  
21 addition, the intensity of  $\text{H}_2$  consumption peak also increases with the increasing of  
22  $\text{MnO}_x$  loading amounts. Based on the above results of  $\text{H}_2$ -TPR, transition metal

1 oxides show high redox property owing to different chemical valence states of  
2 transition metal. The catalytic activity is possibly associated with the changing  
3 capacity of varied oxidation states and with “oxygen mobility” in the oxide lattice.  
4 This property may contribute to the enhancement of catalytic activity for soot  
5 combustion.

### 6 *3.1.7 The results of XPS*

7 Figure 9Aa displays the XPS spectrum of Mn 2p for 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalysts.  
8 The Mn 2p spectrum is significantly broadened and showed some asymmetry towards  
9 both Mn 2p<sub>3/2</sub> and Mn 2p<sub>1/2</sub> peaks. The binding energies of the XPS Mn 2p<sub>3/2</sub> peak are  
10 found to be in the range 639.0-645.0 eV. Two kinds of Mn species including Mn<sup>3+</sup> (ca.  
11 641.5eV), and Mn<sup>4+</sup> (644.5 eV) are presented on the surface of as-prepared catalysts.  
12 Meanwhile, the Mn 2p<sub>1/2</sub> peak also shows two kinds of Mn species at BEs range of  
13 650-657 eV.<sup>22</sup> From Figure 9Ab, it can be seen that the Fe 2p spectrum of Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>  
14 is split into 2p<sub>3/2</sub> (710.6 eV) and 2p<sub>1/2</sub> (724.1 eV) doublets due to the spin-orbit  
15 coupling. According to the previous reports, the remarkable features of Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> in  
16 XPS spectrum is a characteristic of Fe<sup>3+</sup> in Fe<sub>2</sub>O<sub>3</sub>.<sup>51</sup> In addition, there is a satellite  
17 peak at 718.9 eV beside the main peak of Fe 2p<sub>3/2</sub> at 710.9 eV, which is also an  
18 evidence for Fe<sup>3+</sup> in Fe<sub>2</sub>O<sub>3</sub>. The XPS result of Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> is also in good agreement  
19 with the XRD result. As shown in Figure 9Ac, two spin orbit components of Co (Co  
20 2p<sub>3/2</sub> at 779.6 eV and Co 2p<sub>1/2</sub> at 795.1 eV) and two weak satellites at higher energy  
21 (786-790 and 800-805 eV) for both Co peaks are obtained. The BE difference  
22 between Co 2p<sub>1/2</sub> and Co 2p<sub>3/2</sub> peaks is 15.5 eV, and it is in agreement with previously

1 reported for  $\text{Co}_3\text{O}_4$ .<sup>52,53</sup> The Ni 2p XPS spectrum (Figure 9Ad) shows two  
2 characteristic double peaks of Ni 2p<sub>1/2</sub> and Ni 2p<sub>3/2</sub>. The additional peak located at  
3 around 879.2 eV and 860.8 eV are the satellite of Ni 2p<sub>1/2</sub> and Ni 2p<sub>3/2</sub>.<sup>54</sup> According to  
4 the literature, the satellite peaks of Ni 2p<sub>1/2</sub> and Ni 2p<sub>3/2</sub> indicate that Ni<sup>3+</sup> ions or  
5 Ni<sup>2+</sup>-OH species is present in NiO/SiO<sub>2</sub>. Here, the Ni<sup>3+</sup> only refers to a structure  
6 containing vacancies in the NiO but does not indicate an existence of Ni<sub>2</sub>O<sub>3</sub> phase in  
7 NiO/SiO<sub>2</sub>.<sup>55</sup> Figure 9Ae shows the spin-orbit split of Cu 2p<sub>1/2</sub> and Cu 2p<sub>3/2</sub> at 954.6 eV  
8 and 934.5 eV, respectively. The gap between Cu 2p<sub>1/2</sub> and Cu 2p<sub>3/2</sub> is 20.1 eV, which is  
9 similar with the standard spectrum of CuO. The existence of satellite peaks (943.7 and  
10 962.5 eV) is an indicator of the Cu<sup>2+</sup> ions, which is excluded the possibility of Cu<sub>2</sub>O  
11 phase in CuO/SiO<sub>2</sub> catalyst.<sup>56</sup>

12 The corresponding O 1s XPS spectra are present in Figure 9B. Three types of O  
13 species is defined as O-I, O-II and O-III. The O-I component located at 529.5 eV are  
14 ascribed to lattice oxygen ions bonded to transition metal cations<sup>57</sup>. Because of  
15 different transition metals, the BEs of O-I have a small shift from 529.4 to 530.4 eV.  
16 The dominating O-II component at BEs 532.6~ 533.1 eV is obviously related to O<sup>2-</sup>  
17 species in SiO<sub>2</sub> (Si-O-Si environments).<sup>58</sup> The minor O-III component located at  
18 ~535.1 eV may include contributions from Si-OH groups. As shown in Figure 9C, the  
19 values of BEs for Si 2p are changed with different transition metals. The Si 2p spectra  
20 of the catalysts (Figure 9C) are dominated by a peak centered at BEs of 103.0~103.6  
21 eV, characteristic of Si<sup>4+</sup> in SiO<sub>2</sub>. The reason for shifted BEs is that different transition  
22 metals change the chemical environment of Si-O-Si bands. In addition, as shown in

1 Table S1, the surface compositions of as-prepared catalysts are different with bulk  
2 composition. The surface oxygen ratios are higher than corresponding bulk oxygen  
3 ratios, indicates that as-prepared catalysts will exhibit high catalytic activity for soot  
4 combustion.

## 5 3.2 Activity test

### 6 3.2.1 Catalytic activities for soot combustion

7 The catalytic activities of 3DOM SiO<sub>2</sub>-supported transition metal catalysts for soot  
8 oxidation were evaluated and the results are listed in Table 3. To compare the catalytic  
9 activities of as-prepared catalysts, the combustion reactions of pure soot and 3DOM  
10 SiO<sub>2</sub> were also estimated under the same reaction conditions. For the pure soot, the  
11 T<sub>10</sub>, T<sub>50</sub> and T<sub>90</sub> are 482, 564 and 609 °C, respectively. The 3DOM SiO<sub>2</sub> also shows  
12 somewhat catalytic activity for soot combustion, and the T<sub>10</sub>, T<sub>50</sub> and T<sub>90</sub> are 354, 503  
13 and 550 °C, respectively. This result indicates that the 3DOM structure of SiO<sub>2</sub> can  
14 enhance the contact area between soot and reaction gas when the soot and SiO<sub>2</sub> are  
15 met. All the 3DOM SiO<sub>2</sub>-supported transition metal catalysts show high catalytic  
16 activities for soot combustion. However, different SiO<sub>2</sub>-supported transition metal  
17 catalysts exhibit various catalytic activities. Compared the values of  $\Delta T_{10}$ ,  $\Delta T_{50}$  and  
18  $\Delta T_{90}$  of 3DOM SiO<sub>2</sub>-supported transition metal catalysts in the Table 3, 3DOM  
19 MnO<sub>x</sub>/SiO<sub>2</sub> catalyst shows the highest catalytic activity for soot combustion, the  $\Delta T_{10}$ ,  
20  $\Delta T_{50}$  and  $\Delta T_{90}$  of are 173, 202 and 212 °C, respectively. These results suggest that  
21 MnO<sub>x</sub> is optimal choice for soot combustion in those transition metal oxides. In  
22 addition, 3DOM SiO<sub>2</sub>-supported transition metal catalysts show much higher CO<sub>2</sub>

1 selectivity for soot combustion than that of pure soot combustion, and the values are  
2 all surpassed 90%. The CO<sub>2</sub> selectivity value of 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst is as high  
3 as 95.5%. These experimental results suggest that 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst is  
4 promising catalysts for soot combustion. In order to more clearly describe the results  
5 of Table 3, the CO<sub>2</sub> concentration profiles for soot combustion over 3DOM  
6 SiO<sub>2</sub>-supported transition metal catalysts were listed in the Figure S1. From Figure  
7 S1A, it can be seen that the CO<sub>2</sub> concentration profiles are corresponding to the results  
8 of Table 3. 3DOM SiO<sub>2</sub>-supported transition metal catalysts with various transition  
9 metal exhibit different catalytic activities. As shown in Figure S1B, the changing  
10 tendency of catalytic activities is very similar to the result of Table 3.

11 As shown in Table 3, the catalytic activities of 3DOM SiO<sub>2</sub>-supported transition  
12 metal catalysts with varied transition metal oxides follow the order: MnO<sub>x</sub>/SiO<sub>2</sub> >  
13 Co<sub>3</sub>O<sub>4</sub>/SiO<sub>2</sub> > Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> > CuO/SiO<sub>2</sub> > NiO/SiO<sub>2</sub>. Combined the results of TEM  
14 (Figures 4) and H<sub>2</sub>-TPR (Figures 8b-f), the different particle sizes, redox properties of  
15 transition metal oxides and valence state of transition metal element can explain the  
16 varied catalytic activities of 3DOM SiO<sub>2</sub>-supported transition metal catalysts. The  
17 H<sub>2</sub>-TPR results of as-prepared catalysts indicate that CuO/SiO<sub>2</sub> may give the highest  
18 catalytic activity for soot combustion due to the lowest reduction temperature among  
19 those catalysts. However, TEM image of CuO/SiO<sub>2</sub> exhibits that bulk CuO is formed,  
20 which is disadvantage for soot combustion owing to low contact effect between soot  
21 and catalyst. In addition, previous reports have proved that CuO does not have the  
22 capacity of adsorbing oxygen.<sup>59,60</sup> Therefore, CuO/SiO<sub>2</sub> catalyst presents very low

1 activity for particulate matter oxidation. TEM image of  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  displays that  
2  $\text{Fe}_2\text{O}_3$  NPs with particle size of 4-13 nm are highly dispersed on the wall of 3DOM  
3  $\text{SiO}_2$ . This result suggests that soot and  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  catalyst may be well contacted  
4 with soot. And 3DOM  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  catalyst is presumed to show high catalytic activity.  
5 In fact, it exhibits lower catalytic activity than  $\text{MnO}_x/\text{SiO}_2$  and  $\text{Co}_3\text{O}_4/\text{SiO}_2$  catalysts.  
6 The reason for this phenomenon is that 3DOM  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  catalyst shows the highest  
7 reduction temperature among those catalysts. Based on the above two reasons, 3DOM  
8  $\text{Fe}_2\text{O}_3/\text{SiO}_2$  catalyst exhibits low catalytic activity for soot combustion. Except for  
9 particle sizes and redox properties, the valence states also exhibit significant influence  
10 on catalytic activity. As shown in the results of XPS, there are two kinds of valence  
11 states for  $\text{MnO}_x/\text{SiO}_2$  while only one kind of valence state for other catalysts. The  
12 catalyst with different valence states will enhance the capability of oxygen activation.  
13 In the process of soot combustion, the redox reaction of  $\text{Mn}^{3+}/\text{Mn}^{4+}$  in the  $\text{MnO}_x/\text{SiO}_2$   
14 is in favor of forming oxygen vacancies on the surface of catalysts, and then the active  
15 oxygen can be easily generated on the vacancies sites. Therefore,  $\text{MnO}_x/\text{SiO}_2$  shows  
16 the highest catalytic activity for soot combustion.

17 In order to demonstrate the impaction of NO, we also tested the catalytic  
18 performance of  $\text{MnO}_x/\text{SiO}_2$  under different reaction conditions, and the results are  
19 listed in the following Table S2. Compared with pure soot, the  $\text{MnO}_x/\text{SiO}_2$  catalyst  
20 shows super catalytic activity for soot combustion when they reacted under the same  
21 reaction conditions (2000 ppm NO, 10%  $\text{O}_2$ ). This result indicates that our prepared  
22 catalysts exhibit high catalytic performance for soot combustion when NO is

1 participated in soot combustion. As shown in Table S2, the catalytic activities of  
2  $\text{MnO}_x/\text{SiO}_2$  catalyst decrease with the decreasing of concentrations of NO. However,  
3 the catalytic activity of  $\text{MnO}_x/\text{SiO}_2$  is also much higher than pure soot even no NO is  
4 participated in the reaction. Those above results obviously demonstrate that the  
5 reaction pathways of soot combustion can be divided into two parts: One is that active  
6 oxygen species directly oxidize soot particles; the other one is that  $\text{NO}_2$  acts as  
7 intermediate to catalyze soot oxidation.

8 The  $\text{MnO}_x$  loading amount has a significant effect on the catalytic performance of  
9 3DOM  $\text{MnO}_x/\text{SiO}_2$ . The catalytic activity first increases with the increasing  $\text{MnO}_x$   
10 loadings (molar ratio of Mn to Si is 1:4), and then it decreases with further increasing  
11 of  $\text{MnO}_x$  loading amount. The  $\text{H}_2$ -TPR results of 3DOM  $\text{MnO}_x/\text{SiO}_2$  with different  
12  $\text{MnO}_x$  loadings indicate that high  $\text{MnO}_x$  loadings give large amount of  $\text{H}_2$   
13 consumption, which can increase the catalytic activity for soot combustion. However,  
14 there is a suitable  $\text{MnO}_x$  loading amount for the catalyst to get high catalytic activity.  
15 Combined the TEM results in Figure 5, the particle sizes of  $\text{MnO}_x$  NPs increase from  
16 20 nm to 150 nm with increasing  $\text{MnO}_x$  loadings (molar ratio of Mn to Si increased  
17 from 1:16 to 1:2). The free spread of soot particles in 3DOM structure would be  
18 blocked by big  $\text{MnO}_x$  NPs (150 nm) owing to 90-140 nm of interconnected windows  
19 in 3DOM  $\text{MnO}_x/\text{SiO}_2$  (Figure 3). According to the above reasons, 3DOM  $\text{MnO}_x/\text{SiO}_2$   
20 catalyst (molar ratio of Mn to Si is 1:4) exhibits the highest catalytic activity.

### 21 *3.2.2 Stability of 3DOM $\text{MnO}_x/\text{SiO}_2$ catalyst*

22 In order to demonstrate the stability of as-prepared catalysts, the catalytic activity

1 and CO<sub>2</sub> selectivity of 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst in five cycles were examined and  
2 the results are shown in Figure 10. The catalytic activity and CO<sub>2</sub> selectivity of  
3 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst keep constant after reaction for five times under the  
4 condition of loose contact between catalysts and soot particles. The temperature  
5 values of T<sub>10</sub>, T<sub>50</sub> and T<sub>90</sub> are 297 ± 5, 355 ± 6 and 393 ± 5 °C, respectively. Meanwhile,  
6 the CO<sub>2</sub> selectivity value is higher than 95% even after five-cycle reaction. The  
7 stability test results indicate that 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst has good stability for  
8 soot combustion.

### 9 *3.2.3 The effect of 3DOM structure in as-prepared catalysts on soot* 10 *combustion*

11 As a gas-solid-solid reaction, soot combustion is affected by two factors, including  
12 redox property of catalyst and contact efficiency between soot and catalyst. Besides  
13 the high redox property, the contact between soot and catalysts also plays an  
14 important role in improving the catalytic activity. Because loose contact between soot  
15 particles and catalysts is a main way of contact in the process of after-treatment for  
16 diesel engine exhaust, it is extremely important to study and design the active  
17 catalysts, which can improve the contact efficiency between the catalysts and soot  
18 particles under loose contact conditions. In this work, 3DOM SiO<sub>2</sub>-supported  
19 transition metal catalysts with uniform macropores are designed and synthesized to  
20 enhance the contact efficiency. As shown in Figure 2 and Figure 4, the average  
21 diameter of ordered macroporous is about 310 nm and diameter of transition metal  
22 oxides NPs is lower than 50 nm (except for Co<sub>3</sub>O<sub>4</sub>/SiO<sub>2</sub> and CuO/SiO<sub>2</sub>). Therefore,

1 soot particles could easily access those macropores and contact with transition metal  
2 oxides NPs (supported on the wall of 3DOM SiO<sub>2</sub>). To demonstrate the macroporous  
3 effect, the soot and 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst was studied under the same conditions  
4 of TPO reaction to demonstrate the contact efficiency. In this confirmatory experiment,  
5 the reaction temperature of soot and 3DOM catalyst was programmed to 290 °C,  
6 which means the soot was not ignited. From the TEM image of Figure 11a, it can be  
7 seen that soot particles entered into the macropores of 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst. In  
8 addition, the outside soot particles could enter the inner pores of 3DOM catalyst with  
9 the help of the reaction gas flow (O<sub>2</sub>, NO and Ar) during the reaction process owing to  
10 a gas-solid-solid reaction for soot combustion. More importantly, the rising reaction  
11 temperature may be contributed to accelerating the movement of soot particles. Under  
12 the influence of gas flow and rising temperature, the outside soot particles can easily  
13 enter into the 3DOM structure and contact the inner active sites of 3DOM catalyst. As  
14 shown in the Figure 11b, the macropores of 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> are well contacted  
15 with soot particles, indicating that 3DOM structure is a desirable feature for diesel  
16 soot combustion. As shown in the HRTEM images (Figure 11c), the soot and MnO<sub>x</sub>  
17 NPs are well contact with each other in the inner of 3DOM structure. Therefore, the  
18 number of available active sites of catalysts can be maximized through macroporous  
19 effect, especially for inner active sites of catalysts. More active sites would result in  
20 higher catalytic activity. TEM results directly demonstrate that soot particles can  
21 easily enter the interior of 3DOM catalysts with the help of the airflow in the reaction  
22 process under the loose contact conditions, and have less resistance to go through the

1 catalyst structure. In fact, our group has synthesized a series of 3DOM materials and  
2 they show higher catalytic activities than the corresponding particle materials.  
3 Therefore, it is significantly important to study and design 3DOM structure for soot  
4 combustion.

#### 5 4. Conclusions

6 In summary, 3DOM SiO<sub>2</sub> support was successfully synthesized by CCT method.  
7 Different transition metal oxides NPs with varied sizes are supported on the skeleton  
8 of 3DOM SiO<sub>2</sub> by simple incipient-wetness impregnation method. All 3DOM  
9 SiO<sub>2</sub>-supported transition metal catalysts show high periodical arrayed macropores  
10 and interconnected small windows. 3DOM SiO<sub>2</sub>-supported catalysts with different  
11 transition metal oxides NPs exhibit different catalytic activities for soot combustion.  
12 Compared with pure soot, 3DOM MnO<sub>x</sub>/SiO<sub>2</sub> catalyst with molar ratio of Mn:Si is 1:4  
13 shows the highest catalytic activity among the as-prepared catalysts, which T<sub>10</sub>, T<sub>50</sub>  
14 and T<sub>90</sub> are 297, 355 and 393 °C, respectively. The CO<sub>2</sub> selectivity of as-prepared  
15 catalysts is also higher than 93%. The macroporous effects of 3DOM structure, redox  
16 properties of transition metal oxides and sizes of transition metal oxide NPs  
17 significantly affect the catalytic activity for soot combustion simultaneously. The  
18 as-prepared catalysts are promising for practical applications in the catalytic oxidation  
19 of diesel soot particles owing to high activity and low cost.

Table 1 Expression ways of nominal ratio for the preparation of 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts

Table 2 Physicochemical properties of as-prepared catalysts

Table 3 Catalytic activities of 3DOM SiO<sub>2</sub>-supported transition metal catalysts for soot combustion

**Table 1 Expression ways of nominal ratio for the preparation of 3DOM SiO<sub>2</sub>-supported transition metal oxide catalysts**

Catalysts	Kinds of Nitrates	<sup>b</sup> M:Si	M(NO <sub>3</sub> ) <sub>x</sub> /g	3DOM SiO <sub>2</sub> /g
MnO <sub>x</sub> /SiO <sub>2</sub>	<sup>a</sup> Mn(NO <sub>3</sub> ) <sub>2</sub>	1:4	0.7516	0.5
Fe <sub>2</sub> O <sub>3</sub> /SiO <sub>2</sub>	Fe(NO <sub>3</sub> ) <sub>3</sub> ·9H <sub>2</sub> O	1:4	0.6112	0.5
Co <sub>3</sub> O <sub>4</sub> /SiO <sub>2</sub>	Co(NO <sub>3</sub> ) <sub>2</sub> ·6H <sub>2</sub> O	1:4	0.8484	0.5
NiO/SiO <sub>2</sub>	Ni(NO <sub>3</sub> ) <sub>2</sub> ·6H <sub>2</sub> O	1:4	0.6106	0.5
CuO/SiO <sub>2</sub>	Cu(NO <sub>3</sub> ) <sub>2</sub> ·3H <sub>2</sub> O	1:4	0.5074	0.5
MnO <sub>x</sub> /SiO <sub>2</sub> -1	Mn(NO <sub>3</sub> ) <sub>2</sub>	1:16	0.1879	0.5
MnO <sub>x</sub> /SiO <sub>2</sub> -2	Mn(NO <sub>3</sub> ) <sub>2</sub>	1:8	0.3758	0.5
MnO <sub>x</sub> /SiO <sub>2</sub> -4	Mn(NO <sub>3</sub> ) <sub>2</sub>	1:3	1.1274	0.5
MnO <sub>x</sub> /SiO <sub>2</sub> -5	Mn(NO <sub>3</sub> ) <sub>2</sub>	1:2	1.5032	0.5

a: 50 wt% Mn(NO<sub>3</sub>)<sub>2</sub> aqueous solution

b: Molar ratio of transition metal elements to SiO<sub>2</sub>, M means transition metal elements

**Table 2 Physicochemical properties of as-prepared catalysts**

Catalysts	Surface area (m <sup>2</sup> /g) <sup>a</sup>	Total pore volume (cm <sup>3</sup> /g) <sup>b</sup>	Pore size (nm) <sup>c</sup>
SiO <sub>2</sub>	270.1	0.231	8.2
MnO <sub>x</sub> /SiO <sub>2</sub>	180.5	0.208	7.6
Fe <sub>2</sub> O <sub>3</sub> /SiO <sub>2</sub>	215.4	0.135	7.8
Co <sub>3</sub> O <sub>4</sub> /SiO <sub>2</sub>	145.7	0.117	6.9
NiO/SiO <sub>2</sub>	156.7	0.129	6.8
CuO/SiO <sub>2</sub>	136.5	0.099	6.5

a: Calculated by BET method; b: Calculated by BJH desorption cumulative volume of pores between 1.7 nm and 300 nm diameter; c: Calculated by BJH desorption average pore diameter

**Table 3 Catalytic activities of 3DOM SiO<sub>2</sub>-supported transition metal catalysts for soot combustion**

Catalysts	T <sub>10</sub> /°C	T <sub>50</sub> /°C	T <sub>90</sub> /°C	SCO <sub>2</sub> <sup>m</sup> /%	ΔT <sub>10</sub>	ΔT <sub>50</sub>	ΔT <sub>90</sub>
Pure soot	482	564	609	71.6	--	--	--
3DOM SiO <sub>2</sub>	354	503	550	78.1	128	61	59
MnO <sub>x</sub> /SiO <sub>2</sub>	297	355	393	95.5	185	209	216
Fe <sub>2</sub> O <sub>3</sub> /SiO <sub>2</sub>	316	420	480	93.8	166	144	129
Co <sub>3</sub> O <sub>4</sub> /SiO <sub>2</sub>	309	362	397	96.9	173	202	212
NiO/SiO <sub>2</sub>	348	449	496	96.4	134	115	113
CuO/SiO <sub>2</sub>	325	410	452	96.6	157	154	157
MnO <sub>x</sub> /SiO <sub>2</sub> -1	306	382	427	93.1	176	182	182
MnO <sub>x</sub> /SiO <sub>2</sub> -2	304	377	416	94.5	178	187	193
MnO <sub>x</sub> /SiO <sub>2</sub> -4	297	358	397	94.6	185	206	212
MnO <sub>x</sub> /SiO <sub>2</sub> -5	303	361	398	95.6	179	203	211

ΔT<sub>10</sub>: The difference value of T<sub>10</sub> between pure soot and catalysts

ΔT<sub>50</sub>: The difference value of T<sub>50</sub> between pure soot and catalysts

ΔT<sub>90</sub>: The difference value of T<sub>90</sub> between pure soot and catalysts
