1 **Abstract:** We report on the phase formation of  $\text{Ba}_2(\text{Gd,Tb})_2\text{Si}_4\text{O}_{13}$  solid-solution,  
2 and the coexistence of  $\text{Eu}^{2+}/\text{Eu}^{3+}$  was identified after Eu ions doping although the  
3 samples were prepared in a reducing atmosphere. Under 377 nm near-ultraviolet  
4 (UV) light excitation,  $\text{Ba}_2\text{Tb}_2\text{Si}_4\text{O}_{13}$  exhibits the characteristic emission originating  
5 from  $\text{Tb}^{3+}$  corresponding to  $^5\text{D}_4\text{-}^7\text{F}_{6,5,4,3}$  transitions; whereas  $\text{Ba}_2\text{Tb}_2\text{Si}_4\text{O}_{13}:\text{Eu}$  emits  
6 bright red emission from  $\text{Eu}^{3+}$  with peaks around 594, 613 and 623 nm. Accordingly,  
7 photoluminescence tuning of the Eu-doped  $\text{Ba}_2(\text{Gd,Tb})_2\text{Si}_4\text{O}_{13}$  phosphors has been  
8 realized from the green, yellow, orange, to red emission light. Decay time and  
9 time-resolved luminescence results revealed that the tunable luminescence behavior  
10 should be ascribed to the existence of energy migration in the terbium subset, and  
11 successive energy transfer process  $\text{Eu}^{2+}\text{-Eu}^{3+}(\text{Tb}^{3+})$  and  $\text{Tb}^{3+}\text{-Eu}^{3+}$  appear to occur in  
12 the  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  ( $y = 0\text{-}0.12$ ) solid-solution phosphors under investigation.

13

## 1 1. Introduction

2 Lanthanide-doped inorganic phosphor materials have attracted much attention  
3 in recent years owing to their potential applications in display technology, solid state  
4 lighting, and other fields.<sup>1-2</sup> Amongst them, Eu ions have been widely used as  
5 activators because both  $\text{Eu}^{3+}$  and  $\text{Eu}^{2+}$  can function as emission centers in the host  
6 lattices.<sup>3</sup> Comparing with the 4f-5d transition of  $\text{Eu}^{2+}$ , the emission of the 4f-4f  
7 transition of  $\text{Eu}^{3+}$  is relatively insensitive to the host and temperature because the 4f  
8 shell is shielded by the outer filled 5s and 5p shells. However, the 4f-5d transition of  
9  $\text{Eu}^{2+}$  is parity allowed and therefore intense emission bands can be achieved. In  
10 addition, for  $\text{Eu}^{2+}$  the absorption and emission wavelengths of can be tuned by the  
11 host lattice because of the strong interaction between the 5d electron and the ligand  
12 anions through covalency and crystal field.  $\text{Eu}^{3+}$  ions are employed in luminescent  
13 devices such as fluorescent lamps and cathode ray tubes, and phosphors containing  
14  $\text{Eu}^{3+}$  ions as activators can emit red light; their excitation bands usually consist of  
15 host lattice excitation bands, charge-transfer bands, and direct excitation bands of  
16  $\text{Eu}^{3+}$  ions.<sup>4</sup> However, the low oscillator strength and narrow line width of  $\text{Eu}^{3+}$  4f-4f  
17 absorption transitions leads to a weak absorption in the near-UV and blue region.<sup>5</sup> As  
18 a comparison,  $\text{Eu}^{2+}$  emits in the UV- to visible region and the emission wavelength  
19 strongly depends on the nature of the host lattice due to the participation of *d*  
20 orbitals. Therefore, as the characteristic broad-band transition excitation and  
21 emission of  $\text{Eu}^{2+}$  have been well recognized, and it might be very exciting and  
22 interesting if an efficient  $\text{Eu}^{2+}$ - $\text{Eu}^{3+}$  energy transfer can occur in a single-phase

1 valence-varied Eu-doped phosphor, which can provide an opportunity to tailor the  
2 absorption of red-emitting phosphors containing  $\text{Eu}^{3+}$  ions. However, the existence  
3 of metal–metal charge transfer (MMCT) effect will quench the luminescence of the  
4 sensitizer for the designed  $\text{Eu}^{2+}$ - $\text{Eu}^{3+}$  energy transfer. Therefore, Setlur firstly  
5 proposed that energy migration in the terbium subset can be used as an intermediate  
6 to alleviate the MMCT effect.<sup>6</sup> After that, such a strategy has been realized in  
7  $\text{Ba}_3\text{Ln}(\text{PO}_4)_3:\text{Ce}^{3+}, \text{Tb}^{3+}, \text{Eu}^{3+}$ ,  $\text{LnPO}_4:\text{Ce}^{3+}, \text{Tb}^{3+}, \text{Eu}^{3+}$ , and  $\text{Ba}_2(\text{Ln}_{1-z}\text{Tb}_z)(\text{BO}_3)_2\text{Cl}:\text{Eu}$   
8 phosphors systems, and some interesting luminescence properties have been  
9 observed.<sup>7-8</sup> In the present work, Eu-doped  $\text{Ba}_2(\text{Gd}, \text{Tb})_2\text{Si}_4\text{O}_{13}$  solid-solution  
10 phosphors have been designed, the coexistence of  $\text{Eu}^{2+}/\text{Eu}^{3+}$  has been evidenced and  
11 energy transfer of  $\text{Eu}^{2+}$ - $\text{Eu}^{3+}(\text{Tb}^{3+})$  and  $\text{Tb}^{3+}$ - $\text{Eu}^{3+}$  has been observed.

12 The crystal structures of the  $\text{Ba}_2\text{Gd}_{2-x}\text{Tb}_x\text{Si}_4\text{O}_{13}$  phase under investigation were  
13 derived from the  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  phase via Gd/Tb substitution.  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  possesses  
14 a monoclinic structure and a space group  $C2/c$  with lattice parameters  $a = 12.896(3)$   
15  $\text{Å}$ ,  $b = 5.212(1) \text{ Å}$ ,  $c = 17.549(4) \text{ Å}$ ,  $\beta = 104.08(3) \text{ Å}$ .<sup>9</sup> Up to now, several studies  
16 regarding the luminescence properties of rare earth doped  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  have been  
17 reported. Guo et al. investigated the tunable photoluminescence properties of  
18  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}:\text{Ce}^{3+}, \text{Tb}^{3+}$ ,<sup>10</sup> and the spectroscopic properties of  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}:\text{Eu}^{3+}$ .<sup>11</sup>  
19 Zhang et al. studied the vacuum UV spectroscopic properties of  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}:\text{Ln}^{3+}$   
20 ( $\text{Ln}^{3+} = \text{Ce}^{3+}, \text{Tb}^{3+}, \text{Dy}^{3+}, \text{Eu}^{3+}, \text{Sm}^{3+}$ ).<sup>12</sup> In 2015, Zhou et al. studied the green  
21 emitting phosphor  $\text{BaGd}_2\text{Si}_4\text{O}_{13}:\text{Eu}^{2+}$ .<sup>13</sup> Herein, we have investigated the phase  
22 formation of  $\text{Ba}_2(\text{Gd}, \text{Tb})_2\text{Si}_4\text{O}_{13}$ , and the coexistence of  $\text{Eu}^{2+}/\text{Eu}^{3+}$ ; the energy

1 transfer processes  $\text{Eu}^{2+}\text{-Eu}^{3+}(\text{Tb}^{3+})$  and  $\text{Tb}^{3+}\text{-Eu}^{3+}$  in  $\text{Ba}_2\text{Tb}_2\text{Si}_4\text{O}_{13}$  were investigated  
2 in detail.

3

## 4 **2. Experimental section**

### 5 **2.1 Sample preparation**

6  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$  and  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  phosphors were synthesized by high  
7 temperature solid-state reaction, starting from a mixture containing  
8 commercially-available  $\text{BaCO}_3$  (99.9%),  $\text{Gd}_2\text{O}_3$  (99.995%),  $\text{SiO}_2$  (99.95%),  $\text{Tb}_4\text{O}_7$   
9 (99.995%) and  $\text{Eu}_2\text{O}_3$  (99.995%) in the given stoichiometric proportions. After  
10 mixing and grinding, the mixtures were placed into an alumina crucible and then  
11 fired in air at 1360 °C for 5 h under a 5% $\text{H}_2/\text{N}_2$  gas mixture. After this, the samples  
12 were furnace-cooled to room temperature, and ground again into powder for the  
13 following measurement.

### 14 **2.2 Characterization methods**

15 The powder X-ray diffraction (XRD) measurements were conducted on a D8  
16 Advance diffractometer (Bruker Corporation, Germany) operating at 40 kV and 40  
17 mA with Cu  $K\alpha$  radiation ( $\lambda = 0.15406 \text{ \AA}$ ), and the scanning rate was fixed at 4°/min.  
18 Diffuse reflectance spectra were measured on a UV-Vis-NIR spectrophotometer  
19 (SHIMADZU UV-3600) attached with an integrating sphere.  $\text{BaSO}_4$  was used as a  
20 reference standard. Room temperature photoluminescence (PL) excitation and  
21 emission spectra were measured on a fluorescence spectrophotometer (F-4600,  
22 HITACHI, Japan) with a photomultiplier tube operating at 400 V, and a 150 W Xe

1 lamp used as the excitation lamp. The time-resolved PL spectra were measured by  
2 the Edinburgh FLS920 spectrofluorometer with the monitoring wavelength of 377  
3 nm, and the room-temperature decay curves were recorded on the same  
4 spectrofluorometer and the corresponding wavelengths (365 nm for  $\text{Eu}^{2+}$  emission,  
5 377 for  $\text{Tb}^{3+}$  emission and 393 nm for  $\text{Eu}^{3+}$  emission) were used to monitor the decay.  
6 The temperature-dependence luminescence properties were measured on the same  
7 spectrophotometer, which was combined with a self-made heating attachment and a  
8 computer-controlled electric furnace. Quantum efficiency was measured using the  
9 integrating sphere on the FLS920 fluorescence spectrophotometer (Edinburgh  
10 Instruments Ltd., UK).

11

### 12 3. Results and discussion

13 Fig. 1(a) and Fig. 1(b) show the typical XRD patterns of the as-prepared  
14  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$  ( $x = 0, 0.5, 1.0, 1.5, 2.0$ ) and  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  ( $y = 0, 0.01,$   
15  $0.03, 0.06, 0.15, 2.0$ ) samples, respectively. It can be found that all the diffraction  
16 peaks of these two series of samples can be exactly assigned to the corresponding  
17 standard data for the hexagonal phase of  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  (ICSD card no. 260737),  
18 indicating that this series of  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$  ( $x = 0, 0.5, 1.0, 1.5, 2.0$ ) solid  
19 solution samples with different Tb/Gd ratios can form a single phase, and a small  
20 amount of Eu also will not change the crystal structure. We find that the characteristic  
21 diffraction peak (1 1 4) shifts to higher diffraction angles from  $29.28^\circ$  to  $29.40^\circ$  for  
22  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$ , while it shifts to lower diffraction angles from  $29.40^\circ$  to  $29.22^\circ$   
23 for  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$ . This variation could be due to the different ionic radii for  
24  $\text{Gd}^{3+}$ ,  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$ , further suggesting that continuous solid solution of

1  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$  and  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  have formed in the crystal structure.

2 The evolution of the unit cell parameters  $a$  and  $V$  of  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$  and  
3  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  are given in Fig. 2(a) and Fig. 2(b), as a function of  $x$  and  $y$ ,  
4 respectively. The linear behavior of the cell parameters illustrate that these two series  
5 of compounds both belong to a continuous iso-structural solid solution. Fig. 2(c)  
6 presents the crystal structure of  $\text{Ba}_2(\text{Gd,Tb})_2\text{Si}_4\text{O}_{13}$ . The structure is based on finite  
7 zigzag-shaped  $C_2$ -symmetric  $\text{Si}_4\text{O}_{13}$  chains and  $\text{Gd}_2\text{O}_{12}$  dimers built of edge-sharing  
8  $\text{GdO}_7$  polyhedra of  $C_1$  symmetry. The [9+1]-coordinated Ba atoms are located in  
9 voids of the atomic arrangement, as highlighted in Fig. 2(d).

10 Room temperature photoluminescence excitation (PLE) and emission (PL)  
11 spectra of the  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}$  phosphors are shown in Fig. 3(a). Upon  
12 excitation at 365 nm, the PL spectra of  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}$  presents a broad band  
13 in the green region (350-600 nm) and several small peaks on the shoulders near 600  
14 nm. It is well known that  $\text{Eu}^{2+}$  ions provide a broad emission band corresponding to  
15 the  $4f^65d-4f^7$  transition, while  $\text{Eu}^{3+}$  ions emit discrete narrow lines belonging to the  
16  $^5\text{D}_0-^7\text{F}_J$  transitions ( $J = 0-6$ ). Moreover, the two excitation spectra for  
17  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}$  give the corresponding typical spectral profile for the two  
18 ions. Although the europium precursor was  $\text{Eu}_2\text{O}_3$  containing the trivalent ion and  
19 the samples were prepared in a reducing atmosphere, it seems that the trivalent  
20 europium coexists with divalent europium in this compound. In order to prove it, a  
21  $\text{Eu}^{3+}$  singly doped  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  phosphor was prepared in air and its PLE and PL  
22 spectra were comparatively investigated. As also shown in Fig. 3(a), there are three

1 narrow peaks centered at 594, 613 and 624 nm in the PL spectrum of  
2  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}^{3+}$  upon 393 nm excitation, which agrees with the position of  
3  $\text{Eu}^{3+}$  emission in  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}^{2+}/\text{Eu}^{3+}$ . Furthermore, the PLE spectral  
4 profile of  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}^{3+}$  is similar to that of  
5  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}^{2+}/\text{Eu}^{3+}$  monitored at 613 nm; this confirms the consistence of  
6  $\text{Eu}^{2+}$  and  $\text{Eu}^{3+}$  in the  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  host when prepared in reducing atmosphere. Fig.  
7 3(b) shows the PLE ( $\lambda_{\text{em}} = 543$  nm) and PL ( $\lambda_{\text{em}} = 377$  nm) spectra of  
8  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Tb}^{3+}$ . The PLE spectrum observed in the range of 200-300 nm  
9 were attributed to the  $4f^8-4f^75d^1$  ( ${}^7F_6-{}^7D$ ) transition of  $\text{Tb}^{3+}$  and those in the range of  
10 300-400 nm were come from the  $4f-4f$  transition of  $\text{Tb}^{3+}$ . The  $\text{Tb}^{3+}$  emission lines are  
11 located at 487 nm, 542 nm, 585 nm, and 624 nm, and are assigned to the  ${}^5D_4-{}^7F_{6,5,4,}$   
12  ${}_3$  transitions, respectively.<sup>14</sup>

13 The decay curves and lifetime values of  $\text{Eu}^{2+}/\text{Eu}^{3+}$  (excitation wavelength 365  
14 nm for  $\text{Eu}^{2+}$  and 393 nm for  $\text{Eu}^{3+}$ ) and  $\text{Tb}^{3+}$  (excitation wavelength 377 nm) in  
15  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}/\text{Tb}$  phosphor are shown in Fig. 4. Since there are several  
16 different cations with variable environments for the doped rare earth ions in this  
17 system, we have tried different exponential functions. It is found that, in order to get  
18 the best fitting (with the confidence coefficient of 99%) and evaluate the decay time,  
19 the experimental curves were fitted by the sum of two exponential decays using the  
20 formula:<sup>15</sup>

$$21 \quad I(t) = A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2) \quad (1)$$

22 where  $I$  is the luminescence intensity,  $A_1$  and  $A_2$  are constants,  $\tau$  is the time,  $\tau_1$  and  $\tau_2$

1 are rapid and slow lifetimes for exponential components, respectively. On this basis,  
2 the effective lifetime constant ( $\tau^*$ ) can be calculated as:<sup>16</sup>

$$3 \quad \tau^* = (A_1\tau_1^2 + A_2\tau_2^2)/(A_1\tau_1 + A_2\tau_2) \quad (2)$$

4 The effective decay time ( $\tau^*$ ) were calculated to be 2.01  $\mu$ s, 1.96 ms, 1.89 ms and  
5 2.21 ms for the  $4f^65d-4f^7$  ( $\text{Eu}^{2+}$  emission at 507 nm) in  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}$ ,  
6  $^5\text{D}_0-^7\text{F}_2$  ( $\text{Eu}^{3+}$  emission at 613 nm) in  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}$ ,  $^5\text{D}_0-^7\text{F}_2$  ( $\text{Eu}^{3+}$  emission  
7 at 613 nm) in  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}^{3+}$ , and  $^5\text{D}_4-^7\text{F}_5$  ( $\text{Tb}^{3+}$  emission at 543 nm) in  
8  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Tb}^{3+}$ , respectively. The decay profile of the  $^5\text{D}_4$  emission for the  
9 latter sample shows a clear rise at short times, due to the slow relaxation from  $^5\text{D}_3$  to  
10  $^5\text{D}_4$ , attributed to multiphonon relaxation in the silicate host containing high frequency  
11 vibrations. The non-exponential character of the decay profiles is presumably due to  
12 the presence of several slightly different sites for the dopants and, in the case of  
13  $\text{Ba}_2\text{Gd}_{1.99}\text{Si}_4\text{O}_{13}:0.01\text{Eu}$ , to possible  $\text{Eu}^{2+}-\text{Eu}^{3+}$  energy transfer processes.

14 The possibility of the  $\text{Eu}^{2+}/\text{Eu}^{3+}$  coexistence can be verified by the luminescence  
15 behavior. Fig. 5(a) shows the PLE and PL spectra of  $\text{Ba}_2\text{Tb}_2\text{Si}_4\text{O}_{13}$ . It can be seen that  
16 the PLE spectrum of  $\text{Tb}^{3+}$  exhibits two obvious broad bands from 200 to 300 nm with  
17 two peaks at 252 and 279 nm and some weak transitions from 300 to 400 nm. Fig. 5(b)  
18 represents the PLE and PL spectra of  $\text{Ba}_2\text{Tb}_{1.97}\text{Si}_4\text{O}_{13}:0.03\text{Eu}$  obtained at different  
19 experimental conditions. When Eu ions with a low concentration ( $y = 0.03$ ) were  
20 introduced into this matrix, the PLE spectrum of  $\text{Ba}_2\text{Tb}_{1.97}\text{Si}_4\text{O}_{13}:0.03\text{Eu}$  phosphor  
21 prepared in reducing atmosphere has been obviously broadened and the intensity of  
22 the sharp lines corresponding to the emission of  $\text{Tb}^{3+}$  has obviously increased.

1 Moreover, the excitation band edge has shifted to 450 nm, showing a broad-band  
2 character. By comparing the two excitation bands of  $\text{Ba}_2\text{Tb}_{1.97}\text{Si}_4\text{O}_{13}:0.03\text{Eu}$  phosphor  
3 obtained at different experimental conditions, there is an obvious difference in the  
4 excitation band owing to the appearance of a broad excitation band, which supports  
5 the existence of  $\text{Eu}^{2+}$ . Upon excitation at 377 nm, the  $\text{Tb}^{3+}$  emission intensity  
6 decreases accompanied by a remarkable increase of the emission intensities at 594,  
7 613, and 624 nm for  $\text{Ba}_2\text{Tb}_{1.97}\text{Si}_4\text{O}_{13}:0.03\text{Eu}$  phosphor, which are the characteristic  
8 red emission peaks of  $\text{Eu}^{3+}$  ions corresponding to the transitions from  ${}^5\text{D}_0$  to  ${}^7\text{F}_J$  ( $J = 1$   
9 and 2).<sup>17</sup> Generally, we can propose that the enhancement of the red-emitting  
10 luminescence can be ascribed to the energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$ .<sup>18-19</sup>  
11 Furthermore, it is notable that the emission intensity of the  $\text{Ba}_2\text{Tb}_{1.97}\text{Si}_4\text{O}_{13}:0.03\text{Eu}$   
12 phosphor prepared in reducing atmosphere is relatively higher than the one of the  
13  $\text{Ba}_2\text{Tb}_{1.97}\text{Si}_4\text{O}_{13}:0.03\text{Eu}$  fired in air, indicating that the efficient energy transfer  
14 between  $\text{Eu}^{2+}$ - $\text{Eu}^{3+}$  ( $\text{Tb}^{3+}$ ) and the  $\text{Eu}^{2+}$  absorption.

15 The diffuse reflectance spectra of  $\text{Ba}_2\text{Gd}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Tb}$  ( $x = 0, 0.5, 1.0, 1.5, 2.0$ )  
16 phosphors are shown in Fig. 6(a). The spectrum of the  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  host shows a  
17 high reflectance in the visible range, and the band gap estimation in the  
18  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  host is shown by the inset in Fig. 6(a). The band gap of the  
19  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$  host can be estimated according to eq 3<sup>20</sup>

$$20 \quad [F(R_\infty)hv]^n = A(hv - E_g) \quad (3)$$

21 where  $hv$  is the photon energy;  $A$  is a proportional constant;  $E_g$  is the value of the  
22 band gap;  $n = 2$  for a direct transition or  $1/2$  for an indirect transition; and  $F(R_\infty)$  is

1 the Kubelka-Munk function defined as<sup>21</sup>

$$2 \quad F(R_\infty) = (1 - R)^2 / 2R = K/S \quad (4)$$

3 where  $R$ ,  $K$ , and  $S$  are the reflection, absorption, and scattering coefficient,  
 4 respectively. From the linear extrapolation of  $[F(R_\infty)/h\nu]^2 = 0$  in the inset of Figure  
 5 6a, the  $E_g$  value was estimated to be about 4.20eV. As  $Tb^{3+}$  ions were doped into the  
 6  $Ba_2Gd_2Si_4O_{13}$  host, a strong absorption in the range of 200-350 nm assigned to the  
 7 the f-d transition of  $Tb^{3+}$  was observed, as found in the excitation spectrum. The  $E_g$   
 8 value gradually increases, and the absorption intensity is enhanced at higher  $Tb^{3+}$  ion  
 9 concentrations. As a comparison,  $Ba_2Tb_{2-y}Si_4O_{13}:yEu$  phosphors show an obvious  
 10 broad absorption band near 400 nm (Fig. 6(b)), which should be caused by the  
 11  $4f^7-4f^65d^1$  transition of  $Eu^{2+}$ .<sup>22</sup> The reflectance spectrum and PLE spectrum indicate  
 12 that the absorption of  $Ba_2Tb_2Si_4O_{13}:Eu$  phosphor matches well with near-UV chips  
 13 for applications in near-UV LEDs.

14 Fig. 7(a) illustrates the emission spectra of  $Ba_2Tb_{2-y}Si_4O_{13}:yEu$  ( $y = 0-0.12$ )  
 15 samples upon excitation at 377 nm. With increasing Eu concentration, one can see  
 16 that the relative emission intensities of  $Tb^{3+}$  becomes weak, whereas the emission  
 17 intensities of  $Eu^{3+}$  firstly increase until they reach saturation at  $y = 0.03$ , reflecting  
 18 the result of energy transfer from  $Tb^{3+}$  to  $Eu^{3+}$ . In addition, it is surprising to find the  
 19 appearance of a broad band centered around 507 nm with increasing  $y$ , which can be  
 20 assigned to the  $4f^65d^1-4f^7$  transition of  $Eu^{2+}$ , further supporting the coexistence of  
 21  $Eu^{2+}$  and  $Eu^{3+}$ .<sup>23</sup> Because of the  $Eu^{2+}-(Tb^{3+})_n-Eu^{3+}$  energy transfer process, the CIE  
 22 coordinates upon 377 nm excitation of  $Ba_2Tb_{2-y}Si_4O_{13}:yEu$  ( $y = 0, 0.01, 0.03, 0.09$ )

1 progressively shifted from green (0.2966, 0.5798) to red (0.5048, 0.3955) with  
 2 increasing  $y$  as displayed in Fig. 7(b). As also given in the photographs of the  
 3 emitting phosphors, the as-observed emitting color is obvious, which means that the  
 4 tunable luminescence can be realized in the novel  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  phosphors via  
 5  $\text{Eu}^{2+}-(\text{Tb}^{3+})_n-\text{Eu}^{3+}$  energy transfer processes.

6 In order to demonstrate the energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$ , the decay curves  
 7 of  $\text{Tb}^{3+}$  emission at 542 nm and  $\text{Eu}^{3+}$  emission at 613 nm of  $\text{Ba}_2\text{Tb}_2\text{Si}_4\text{O}_{13}$  and  
 8  $\text{Ba}_2\text{Tb}_{1.995}\text{Si}_4\text{O}_{13}:0.005\text{Eu}$  phosphors are shown in Fig. 8(a) (Excitation at 377 nm).  
 9 Using Eq 1 and Eq 2, the values of the effective decay time were found to be 2.59,  
 10 0.96 and 1.83 ms for the  $^5\text{D}_4-^7\text{F}_5$  ( $\text{Tb}^{3+}$  emission at 543 nm) in  $\text{Ba}_2\text{Tb}_2\text{Si}_4\text{O}_{13}$ ,  $^5\text{D}_4-^7\text{F}_5$   
 11 ( $\text{Tb}^{3+}$  emission at 543 nm) in  $\text{Ba}_2\text{Tb}_{1.995}\text{Si}_4\text{O}_{13}:0.005\text{Eu}$ , and  $^5\text{D}_0-^7\text{F}_2$  ( $\text{Eu}^{3+}$  emission  
 12 at 613 nm) in  $\text{Ba}_2\text{Tb}_{1.995}\text{Si}_4\text{O}_{13}:0.005\text{Eu}$ , respectively. Accordingly, the energy  
 13 transfer efficiency ( $\eta_T$ ) can be calculated using the following expression:<sup>24</sup>

$$14 \quad \eta_T = 1 - \frac{\tau_x}{\tau_0} \quad (5)$$

15 here  $\tau_0$  and  $\tau_x$  are the corresponding lifetime values of donor  $\text{Tb}^{3+}$  in the absence and  
 16 the presence of the acceptor  $\text{Eu}^{3+}$ , and  $\eta_T$  is the energy transfer efficiency. As shown  
 17 in the inset of Fig. 8(a), the total  $\eta_T$  is found to be 62.9% from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$  in the  
 18  $\text{Ba}_2\text{Tb}_{1.995}\text{Si}_4\text{O}_{13}:0.005\text{Eu}$  phosphor. We also measured the decay curves of the  
 19  $\text{Ba}_2\text{Tb}_{2-y}\text{Si}_4\text{O}_{13}:y\text{Eu}$  phosphors excited at 377 nm, as given in Fig. 8(b). It was found  
 20 that the lifetimes for  $\text{Tb}^{3+}$  decreased with increasing Eu concentraion, which offers  
 21 clear evidence for the presence of energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$ , and the energy  
 22 transfer efficiencies are 62.9%, 68.7%, 73.7%, 81.5% and 89.2% depending on

1 different Eu concentration, 0.005, 0.01, 0.02, 0.03 and 0.06, respectively. Fig. 8(c)  
2 shows the decay curves of the  $^5D_4$ - $^7F_5$  transition of  $Tb^{3+}$  upon excitation at 273, 365,  
3 and 377 nm. Based on the decay curves in Fig. 8(c), Eq 1 and Eq 2, the value of  
4 decay time were calculated to be practically independent of the excitation  
5 wavelength, with values 0.49, 0.45 and 0.48 ms for excitation of 273, 365, and 377  
6 nm, respectively.

7 To study the energy transfer process from  $Tb^{3+}$  to  $Eu^{3+}$  in  $Ba_2TbSi_4O_{13}:Eu$   
8 phosphor in more detail, time-resolved emission spectra of  $Ba_2Tb_{1.995}Si_4O_{13}:0.005Eu$   
9 were measured upon excitation into the  $Tb^{3+}$  band with a delay time ranging from 0  
10 to 3.12 ms (Fig. 9). At  $t = 0$  ms, only the characteristic emission  $Tb^{3+}$  is observed; no  
11  $Eu^{3+}$  emission is present because the excitation energy  $Tb^{3+}$  has not been transferred  
12 yet to  $Eu^{3+}$ . As also shown in Fig. 9, when  $t = 0.78$  ms, the emission of  $Tb^{3+}$  starts to  
13 decrease accompanied by the presence of  $Eu^{3+}$  emissions due to the efficient energy  
14 transfer of  $Tb^{3+}$  to  $Eu^{3+}$ . The emission of  $Tb^{3+}$  decreases gradually with further  
15 increase of the decay time, whereas that of  $Eu^{3+}$  begins to increase due to transfer of  
16 more excitation energy from  $Tb^{3+}$  to  $Eu^{3+}$ . Therefore, the  $Eu^{3+}$  ion acts as the  
17 terminal of the thermal of the energy transfer processes in the  $Ba_2TbSi_4O_{13}:Eu$   
18 phosphor. Thus, we can obtain bright red luminescence in the  $Ba_2TbSi_4O_{13}:Eu$   
19 phosphor upon near UV excitation.

20 Fig. 10 illustrates the energy level model for the energy transfer processes of  
21 and  $Eu^{2+}$ - $Tb^{3+}$ - $Eu^{3+}$  in the  $Ba_2Tb_2Si_4O_{13}$  host. As can be seen from Fig. 10, the  
22 excitation lines of  $Ba_2Tb_2Si_4O_{13}:Eu$  phosphors in the  $n$ -UV region come from the

1 absorption of the combined effect of  $Tb^{3+}$ ,  $Eu^{3+}$ , and  $Eu^{2+}$ , so that a broad and strong  
2 absorption band can be observed in the PLE spectrum (Figure 3b). The energy  
3 absorbed by  $Eu^{2+}$  can also be efficiently transferred from the  $4f^65d^1$  band to the  
4 excited levels of  $Eu^{3+}$  and  $Tb^{3+}$ ; accordingly, the energy absorbed by  $Tb^{3+}$  can be  
5 transferred from the  $^5D_4$  level of  $Tb^{3+}$  to the  $^5D_0$  ( $^5D_1$ ) level of  $Eu^{3+}$ .<sup>25-26</sup>

6 The thermal stability of phosphor is one of the important parameters for  
7 possible applications. For this reason, the emission spectra of the selected  
8  $Ba_2Tb_{1.97}Si_4O_{13}:0.03Eu$  phosphor at various temperatures are shown in Fig. 11(a).  
9 The variations of the relative emission intensities as a function of temperature are  
10 plotted in Fig. 11(b). When the temperature is increased to 150 °C, the PL intensities  
11 of  $Tb^{3+}$  and  $Eu^{3+}$  ions decrease to 94.9% and 88.2% of the corresponding initial value  
12 (25 °C). In Fig. 11(b), we have also given the temperature dependent PL intensities  
13 variation of the commercial  $BaMgAl_{10}O_{19}:Eu^{2+}$  (BAM) blue phosphor, and the  
14 comparable thermal stability can be found. The small intensity decrease indicates  
15 that  $Ba_2Tb_2Si_4O_{13}:Eu$  could be used for high-power LED application. In general, the  
16 thermal quenching of emission intensity can be explained by several mechanisms. A  
17 widely accepted mechanism is the electronic transition through the intersection  
18 between the ground and excited states. In other words this mechanism is described as  
19 a large displacement between the potential energy curves of the ground and excited  
20 state in the configuration coordinate diagram.<sup>27</sup> In the present case, this mechanism  
21 would be valid in the case of excitation in the absorption profile of  $Eu^{2+}$ . To better  
22 understand the thermal quenching phenomena, the activation energy for the thermal

1 quenching was fitted using the equation describing the crossover between Franck  
2 Condon displaced potential energy curves.<sup>28-29</sup>

$$3 \quad I_T = \frac{I_0}{1 + c \exp\left(-\frac{\Delta E}{kT}\right)} \quad (6)$$

4 where  $I_0$  is the initial PL intensity of the phosphor at room temperature,  $I_T$  is the PL  
5 intensity at different temperatures,  $c$  is a constant,  $\Delta E$  is the activation energy for  
6 thermal quenching, and  $k$  is Boltzmann constant ( $8.62 \times 10^{-5}$  eV). According to the  
7 equation, the activation energy  $\Delta E$  can be calculated from a plotting of  $\ln[(I_0/I)-1]$   
8 against  $1/kT$ , where a straight slope equals  $-\Delta E$ . As shown in Fig. 11(b),  $\Delta E$  were  
9 found to be 0.351 and 0.296 eV for  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$ , respectively. The relatively high  
10 activation energy results in a good thermal stability for this phosphor. The quantum  
11 efficiency of the phosphor is another important parameter to be considered for  
12 practical application, and we have also measured the internal quantum efficiency  
13 (QE) of  $\text{Ba}_2\text{Tb}_{2-x}\text{Si}_4\text{O}_{13}:x\text{Eu}$  ( $x = 0, 0.005, 0.03$  and  $0.09$ ) phosphors. The measured  
14 internal QE values are 30.06%, 31.66%, 39.35% and 23.39%, respectively, for  $x = 0,$   
15 0.005, 0.03, 0.09 under 377 nm excitation.

16

#### 17 **4. Conclusion**

18 In summary, color-tunable  $\text{Ba}_2\text{Gd}_{2-x}\text{Tb}_x\text{Si}_4\text{O}_{13}:y\text{Eu}$  solid-solution phosphors  
19 were prepared by the high-temperature solid-state reaction in reducing atmosphere.  
20 The terbium ions in the host can not only form the iso-structural phase originated  
21 from the  $\text{Ba}_2\text{Gd}_2\text{Si}_4\text{O}_{13}$ , but they can be also used to realize the  $\text{Eu}^{2+}-(\text{Tb}^{3+})_n-\text{Eu}^{3+}$   
22 energy transfer channel between broad-band absorption of  $\text{Eu}^{2+}$  and the narrow-line  
23 emission of  $\text{Eu}^{3+}$ . On the basis of this process, the emission color of the obtained

1 phosphors can be varied from green to yellow and finally to red by adjusting the  
2 concentration of Eu. Moreover, the temperature dependence of the luminescence  
3 intensity shows that this phosphor has an excellent thermal stability against  
4 temperature quenching.
