**Abstract** In this work, a rare 2D→3D single-crystal-to-single-crystal transformation (SCSC) is observed in metal-organic coordination complexes, which is triggered by thermal treatment. The 2D two-fold interpenetrating square lattice layer  $[\text{Cd}(\text{IBA})_2]_n$  (**1**) is irreversibly converted into a 3D four-fold interpenetrating diamond framework  $\{[\text{Cd}(\text{IBA})_2(\text{H}_2\text{O})] \cdot 2.5\text{H}_2\text{O}\}_n$  (**2**) (HIBA = 4-(1H-imidazol-1-yl)benzoic acid). Considering two complexes with different interpenetrating structures and dimensionality, their influence on photovoltaic properties are studied. Encouraged by the UV-visible absorption and HOMO–LUMO energy states matched for sensitizing  $\text{TiO}_2$ , the two complexes are employed in combination with N719 in dye-sensitized solar cells (DSSCs) to compensate absorption in the region of ultraviolet and blue-violet, offset competitive visible light absorption of  $\text{I}_3^-$  and reducing charge recombination of injected electron. After co-sensitized with **1** and **2**, the device co-sensitized by **1**/N719 and **2**/N719 yield an overall efficiency of 7.82% and 8.39%, which are 19.94% and 28.68% higher than that of the device sensitized only by N719 (6.52%). Consequently, high dimensional interpenetrating complexes could serve as excellent co-sensitizers and application in DSSCs.

## Introduction

Currently single-crystal-to-single-crystal (SCSC) transformations have attracted the greatest attention in solid-state chemistry and crystal engineering.<sup>1–4</sup> In the process of crystal growth and post-synthetic treatment, due to the tension and shear forces produced by component changes, the brittle single crystal tends to increase mosaicity and even crack into smaller specimen under various chemical and physical stimuli. Such phenomena may become more serious for many flexible complexes exhibiting very significant structural changes. Through the SCSC transformation, new complexes can be gained in a high yield, which cannot be obtained under conventional conditions. Therefore, SCSC transformation is of particular significance and interest.<sup>5–8</sup> Hitherto, a variety of SCSC transformations, such as 0D → 1D/2D, 1D → 2D/3D, and 2D → 3D have been documented.<sup>9–12</sup> These types of structural transformations are associated with the cleavage and regeneration of new coordination bonds and the corresponding change in dimensionality is reflected by small changes in porosity, and optical and thermal stability.<sup>13</sup> In particular, structural transformations involving 2D and 3D frameworks are the more important because most of the complexes with potential properties—such as sensor, catalysis, magnetism, and gas storage, separation—are generally 3D frameworks.<sup>14,15</sup> Meanwhile, the SCSC transformations between interpenetrating structures are still quite rare, since it is difficult to retain their crystallinity after breaking and forming coordination bonds in the solid phase due to interpenetrating structure stability.<sup>16</sup> Therefore, the design and fabrication of the SCSC transformation between 2D → 3D interpenetrating

1 structures is still a big challenge.

2 Based on this idea, we considered Cd(II) to be a good candidate for construction of  
3 complexes due to its more fascinating mode of coordination (coordination number 4-8),  
4 lower-cost and adequate electron transport, of which the complexes have a variety of  
5 structures and favorable properties.<sup>17-21</sup> The enormous variabilities of available ligand–metal  
6 combinations open the possibility of creating SCSC transformations “by design”.  
7 4-(1H-imidazol-1-yl)benzoic acid (HIBA), with the torsional space between the benzene ring  
8 and the imidazole ring, is a versatile ligand with the ability to form interpenetrating structure  
9 due to the position of its functional groups.<sup>22,23</sup> Inspired by this, the reaction strategy of a  
10 thermally induced SCSC transformation, the 2D two-fold interpenetrating square lattice layer  
11  $[\text{Cd}(\text{IBA})_2]_n$  (**1**) is successfully converted to a 3D four-fold interpenetrating diamond  
12 framework  $\{[\text{Cd}(\text{IBA})_2(\text{H}_2\text{O})] \cdot 2.5\text{H}_2\text{O}\}_n$  (**2**) *via* addition of the coordinated water molecule  
13 and rearrangement of coordination bonds. Within the reaction of the HIBA with Cd(II) ion  
14 under thermal treatment condition, the water existed in solvent may easier to coordinate with  
15 the metal center.

16 As the rapid development of energy conversion devices, the complexes are being applied  
17 in the dye sensitized solar cells (DSSCs) gradually. In the photoelectric transformation,  
18 co-sensitization by means of multiple sensitizers including complexes would appear to be  
19 more effective to improve the absorption ability of solar cell.<sup>24</sup> It is found that complexes with  
20 large surface area and interconnected molecules will help to adsorb sufficient dye and provide  
21 a pathway for the transport of electrons, and further improve the photovoltaic properties of  
22 DSSCs when they are used as co-sensitizers. Therefore, the synthesis of co-sensitizers with  
23 high dimensional and pore structures is very important. The structural transformation of one  
24 of these complexes is accompanied by SCSC manner which helps to get high dimensional  
25 structure and framework porosity.<sup>25,26</sup> For example, Yang and coworkers described an  
26 exceedingly rare example of solid-state SCSC transformation from a 2D layer to a known 3D  
27 framework, which brings the free volume up to 33.7%.<sup>27</sup> The colleagues of Lin and Wen  
28 obtained SCSC transformation of the 2D coordination network to the 3D metal–organic  
29 framework *via* dimerization of the metal-connecting points, leading to significant  
30 enhancement in framework porosity.<sup>28</sup> To the best of our knowledge, high dimensional  
31 interpenetrating complexes as co-sensitizers are never investigated. A high dimensional  
32 interpenetrating structure might exhibit high thermal stability and porosity. It is beneficial to  
33 adsorb dye molecules to enhance efficient light harvesting. The excellent properties indicate  
34 the great potential of the high dimensional interpenetrating complexes being utilized as  
35 co-sensitizers in DSSCs fields. In addition, considering ruthenium complex N719 as a typical

1 representative of organic dye used in DSSCs with low utilization in the region of short  
2 wavelength, the complexes as co-sensitizers could not only compensate the absorption spectra  
3 but also overcome the competitive light absorption by  $\Gamma^-/I_3^-$ , avoid dye aggregation and  
4 reduce charge recombination, which will lead to enhanced DSSCs performance.<sup>29</sup> On the  
5 basis of the above considerations, this work initially attempts to use high dimensional  
6 interpenetrating complexes as co-sensitizers for detailed research. Complexes **1** and **2** are  
7 employed as co-sensitizers with N719 dye based solar cell, and the co-sensitized devices  
8 exhibit enhancements of photovoltaic performance. The power conversion efficiency of N719  
9 sensitized DSSCs is enhanced by 19.94% and 28.68% after co-sensitized with **1** and **2** than  
10 that for DSSCs using single N719. As a consequence, the reasonable design and synthesis of  
11 high dimensional interpenetrating complexes with a combination of different optical and  
12 electrochemical properties may provide interesting insight into the development of  
13 high-performance DSSCs devices.

## 14 **Experimental section**

### 15 **Materials and Measurements**

16 All materials and reagents were commercially available and used without further purification.  
17 IR spectra were obtained from KBr pellets using a Nicolet Avatar-360 infrared spectrometer.  
18 Elemental analyses were performed on a Perkin-Elmer 2400 element analyzer. Powder X-ray  
19 diffraction (PXRD) patterns were recorded in the  $2\theta$  range of 5–50° using Cu K $\alpha$  radiation by  
20 Shimadzu XRD-6000 X-ray Diffractometer. The thermal analyses were performed on a  
21 ZRY-2P thermogravimetric analysis under a flow of air from room temperature to 700 °C.  
22 Variable-temperature X-ray powder diffraction (VT-XRPD) patterns were obtained using a  
23 PANalytical X-ray diffractometer, equipped with monochromated Cu K $\alpha$  radiation 40 mA, 40  
24 kV. UV-visible absorption spectra were recorded on SPECORD S600 spectrophotometer  
25 (Jena, Germany) for samples in ethanol solution and UV-2250 spectrophotometer (Shimadzu,  
26 Japan) for sensitized TiO<sub>2</sub> films, respectively. The solid-state photoluminescence analyses  
27 were carried out on an Edinburgh FLS920 fluorescence spectrometer. The cyclic voltammetry  
28 (CV) were measured with a electrochemical workstation (CHI660D, Chenhua, Shanghai)  
29 using a three-electrode cell with a Pt working electrode, a Pt wire auxiliary electrode, and a  
30 saturated calomel reference electrode in saturated KCl solution. The supporting electrolyte  
31 was 0.1 M tetrabutylammonium hexafluorophosphate (TBAPF<sub>6</sub>, Fluka, electrochemical grade)  
32 in ethanol as the solvent. Photocurrent-photovoltage ( $J$ - $V$ ) curves were recorded by Keithley  
33 model 2400 digital source meter using a mask with an aperture area of 0.16 cm<sup>2</sup>. The incident  
34 photon-to-current conversion efficiency (IPCE) was measured on an EQE/IPCE spectral  
35 response system (Newport). Electrochemical impedance spectroscopy (EIS) was recorded by

1 CHI660D Electrochemical Analyzer (Chenhua, China).

## 2 **Assembly of DSSCs**

3 The FTO conducting glass (Fluorine-doped SnO<sub>2</sub>, sheet resistance 15 Ω per square,  
4 transmission 90% in the visible) was purchased from NSG, Japan, and cleaned by a standard  
5 procedure. N719 [cis-bis(isothiocyanato)bis  
6 (2,2-bipyridyl-4,4-dicarboxylato)-ruthenium(II)bis-tetrabutylammonium] was purchased from  
7 Solaronix Company, Switzerland. Dye-sensitized solar cells were fabricated using the  
8 following procedure. Before screen-printing method, FTO substrate was first treated by 20  
9 mM TiCl<sub>4</sub> aqueous solution in order to reduce the recombination between FTO and electrolyte.  
10 The TiO<sub>2</sub> paste was cast onto the FTO substrate by the screen-printing method, and the FTO  
11 substrate was treated by 20 mM TiCl<sub>4</sub> aqueous solution again to optimize the TiO<sub>2</sub> thin film,  
12 followed by drying at 100 °C for 5 min and this process was repeated for six times, then  
13 followed by sintering at 500 °C for 15 min in air to obtain a transparent TiO<sub>2</sub> photoelectrode  
14 with the thickness of ca. 10 μm. The co-adsorbent electrodes were prepared by immersing the  
15 obtained mesoporous TiO<sub>2</sub> photoelectrode into 0.3 mM **1** or **2** solution in absolute ethanol for  
16 2 h and washed with ethanol and dried with blower, then further immersing the electrodes in  
17 0.3 mM N719 solution in absolute ethanol for 12 h, and then washed with ethanol and dried  
18 with blower again. The single N719 sensitized electrodes were prepared by only immersing  
19 TiO<sub>2</sub> photoelectrode into 0.3 mM N719 solution in absolute ethanol for 14 h. The electrolyte  
20 used in this work was 0.5 M LiI + 0.05 M I<sub>2</sub> + 0.1 M *tert*-butyl pyridine in a 1:1 (volume ratio)  
21 of acetonitrile-propylene carbonate. The platinum counter electrode was prepared by  
22 depositing H<sub>2</sub>PtCl<sub>6</sub> paste onto the FTO glass substrates and then sintered at 450 °C for 30 min.  
23 The cells were assembled by sandwiching the electrolyte between the dye sensitized  
24 photoanode and the counter electrode and assembly was held together using mini-binder clips.

## 25 **Synthesis of [Cd(IBA)<sub>2</sub>]<sub>n</sub> (**1**) and {[Cd(IBA)<sub>2</sub>(H<sub>2</sub>O)]·2.5H<sub>2</sub>O}<sub>n</sub> (**2**)**

26 A mixture of Cd(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O (92.4 mg, 0.3 mmol), HIBA (18.8 mg, 0.1 mmol) were  
27 dissolved in 8 mL H<sub>2</sub>O, and stirred for 30 min, then heated in a sealed vial at 80 °C for 6 days.  
28 After slow cooling to room temperature, flavescens block crystals of **1** were obtained with a  
29 yield of 77% (based on HIBA). Anal. Calcd for C<sub>20</sub>H<sub>14</sub>N<sub>4</sub>O<sub>4</sub>Cd (*Mr*: 486.75): C, 49.35; H,  
30 2.90; N, 11.51%. Found: C, 49.38; H, 2.91; N, 11.50%. IR (KBr pellet, cm<sup>-1</sup>, Fig. S1) for **1**:  
31 3436 (br, s), 1698(s), 1609 (vs), 1526(s), 1484(m), 1427(w), 1306(s), 1243(m), 1181(m),  
32 1114(m), 1055(s), 957(s), 847(m), 774(vs), 691(m), 643(s), 524(vs). Freshly prepared  
33 block-type single crystals **1** were transferred into a 15 mL Teflon-lined stainless steel  
34 autoclave and heated to 200 °C for 24 h. Flavescens sheet crystals **2** were obtained with a  
35 yield of 69% (based on HIBA). Anal. Calcd for C<sub>20</sub>H<sub>21</sub>N<sub>4</sub>O<sub>7.5</sub>Cd (*Mr*: 549.82): C, 43.69; H,

1 3.85; N, 10.19%. Found: C, 43.46; H, 3.82; N, 10.17%. IR (KBr pellet,  $\text{cm}^{-1}$ , Fig. S1) for **2**:  
 2 3420 (br, s), 1672(s), 1604 (s), 1552(s), 1520(s), 1401(vs), 1302(s), 1244(w), 1181(w),  
 3 1124(m), 1056(s), 967(m), 852(s), 774(s), 696(w), 649(m), 508(m).

#### 4 X-ray Crystallography

5 The X-ray diffraction data taken at room temperature for complexes **1** and **2** were collected  
 6 on a Rigaku R-Axis RAPID IP diffractometer equipped with graphite-monochromated Mo  
 7  $K\alpha$  radiation ( $\lambda = 0.71073 \text{ \AA}$ ). The structures of **1** and **2** were solved by direct methods and  
 8 refined on  $F^2$  by the full-matrix least squares using the SHELXTL-97 crystallographic  
 9 software.<sup>30,31</sup> Anisotropic thermal parameters are refined to all of the non-hydrogen atoms.  
 10 The hydrogen atoms were held in calculated positions on carbon atoms and nitrogen atoms  
 11 and that were directly included in the molecular formula on water molecules. The CCDC  
 12 1041925, 1041924 contain the crystallographic data **1** and **2** of this paper. These data can be  
 13 obtained free of charge at [www.ccdc.cam.ac.uk/](http://www.ccdc.cam.ac.uk/) deposit. Crystal structure data and details of  
 14 the data collection and the structure refinement are listed as Table 1, selected bond lengths and  
 15 bond angles of **1** and **2** are listed as Table S1.

## 1 Results and discussion

### 2 Structure description: $[\text{Cd}(\text{IBA})_2]_n$ (**1**)

3 Complex **1** contains one  $\text{Cd}^{2+}$  cation, two  $\text{IBA}^-$  anions in the asymmetric unit (Fig. 1a). X-ray  
4 analysis reveals that the central  $\text{Cd}^{2+}$  cation is six-coordinated and forms distorted triangular  
5 prism coordination geometry, completed by four oxygen atoms from carboxylate and two  
6 nitrogen atoms from imidazole groups (Fig. 1b). In **1**, the carboxylate group is completely  
7 deprotonated and adopts a bidentate-chelate fashion. The imidazole ring and phenyl rings of  
8  $\text{IBA}^-$  in a nonplanar fashion, form to left-handed helices (Fig. 1c). The resulting left-handed  
9 helices with a pitch of 16.478 Å are alternately arranged in an equal ratio, extending into a 2D  
10 layer structure (Fig. 1d).

11  
12 **Fig. 1** (a) Asymmetric unit of **1** (hydrogen atoms are omitted for clarity). Symmetry codes: O1A 1.5-x, -y,  
13 -1+z; O1B 1.5-x, -0.5+y, 1.5-z; O2A 1.5-x, -y, -1+z; O2B 1.5-x, -0.5+y, 1.5-z; N1A x, -0.5-y, 0.5-z; N1B  
14 1.5-x, -y, -1+z; N2A x, -0.5-y, 0.5-z. (b) Polyhedral representation of the coordination sphere of the  $\text{Cd}^{2+}$   
15 centre in **1**. (c) The space-filling mode of the left-handed helix in **1**. (d) The illustration of single 2D layer  
16 in **1**.

17 The 2D layer contains two separated sub-layers with the  $\text{Cd}^{2+}$  cation in a common plane.  
18 Two of sub-layers are further parallel to each other. Thus, a two-fold parallel interpenetrating

1 crystalline lattice is afforded (Fig. 2a). Every separated sub-layer is constructed by infinite  
 2 square grids. Thus, **1** exhibits a square grid with square dimensions of  $16.478(3) \times 16.556(3)$   
 3 Å. If the  $\text{Cd}^{2+}$  cation is considered as a 4-connected node and the  $\text{IBA}^-$  anions as the linkers,  
 4 then **1** is simplified to a 4-connected 2D **sql** topological network with the Schläfli symbol of  
 5  $(4^4.6^2)$ . The layers are further stabilized by  $\pi$ - $\pi$  stacking interaction between adjacent  
 6 imidazole rings with distances of 3.495 Å (Fig. 2b).

7  
 8 **Fig. 2** (a) The ball-and-stick and the topological representation of a two-fold parallel interpenetrating layer  
 9 of **1**. (b) The  $\pi$ - $\pi$  interactions between the two face-to-face imidazole rings of  $\text{IBA}^-$  anion.

10 **Structure description:  $[\text{Cd}(\text{IBA})_2(\text{H}_2\text{O})] \cdot 2.5\text{H}_2\text{O}$  (**2**)**

11 The asymmetric unit of complex **2** contains one  $\text{Cd}^{2+}$  cation, two  $\text{IBA}^-$  anions, one  
 12 coordinated water molecule, and two and half free water molecules (Fig. 3a). The Cd1 has a  
 13 pentagonal bipyramid environment, in which contains O1, O2, O3, O4, O5, N1 and N3 from  
 14 two  $\text{IBA}^-$  anions and one coordinated water molecule (Fig. 3b). In **2**, each  $\text{IBA}^-$  anion links  
 15 two adjacent  $\text{Cd}^{2+}$  cations, and four  $\text{IBA}^-$  anions coordinated to one  $\text{Cd}^{2+}$  cation have a  
 16 pseudotetrahedral extension. Thus, a 3D diamond-like network is formed, containing large  
 17 adamantanoid cages (Fig. 3c). A single adamantanoid cage exhibits maximum dimension of  
 18  $35.011(2) \text{ \AA} \times 21.815(1) \text{ \AA}$  (corresponding to the longest intracage  $\text{Cd} \cdots \text{Cd}$  distances). Given  
 19 that the chelating carboxylates are treated as one connecting point, each  $\text{Cd}^{2+}$  cation is  
 20 connected to four adjacent  $\text{Cd}^{2+}$  cations through the four linear  $\text{IBA}^-$  linkers to result in a 3D  
 21 **dia** topology with the point symbol  $6^6$  and the long symbol  $6_2 \cdot 6_2 \cdot 6_2 \cdot 6_2 \cdot 6_2 \cdot 6_2$  (Fig. 3d).

22 In order to minimize the big hollow cavities in **2** and stabilize the overall network, the  
 23 huge chamber facilitates other three independent equivalent networks to interpenetrate,  
 24 generating a four-fold interpenetrated 3D architecture (Fig. S2). Topologically, the structure of

1 **2** consists of **dia** framework, and four independent **dia** nets are interpenetrated within the  
 2 whole structure (Fig. 4). The total void value of the channel without free water molecules is  
 3 estimated to be  $1278.6 \text{ \AA}^3$  by *PLATON*<sup>32,33</sup> software, approximately 25.7% of the total crystal  
 4 volume of  $4968.2 \text{ \AA}^3$ .

5

## 1 Comparison of synthetic conditions and structures

2 The single-crystal-to-single-crystal transformations can be achieved by thermal treatment, the  
3 2D complex  $[\text{Cd}(\text{IBA})_2]_n$  (**1**) is successfully converted to 3D complex  
4  $\{[\text{Cd}(\text{IBA})_2(\text{H}_2\text{O})] \cdot 2.5\text{H}_2\text{O}\}_n$  (**2**) *via* breakage/formation of chemical bonds. This SCSC phase  
5 transition could provide us a good model to study the correlation between the changes in the  
6 crystal interior and its morphology.<sup>34,35</sup> **1** was prepared using  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  and HIBA  
7 ligand at 80 °C under hydrothermal synthetic conditions. As expected, upon heating to 200 °C  
8 under Teflon-lined stainless steel autoclave, **1** undergoes a SCSC transformation to yield the **2**.  
9 The result of single-crystal X-ray diffraction analysis revealed that **1** and **2** crystallizes in the  
10 orthorhombic space group. The most significant molecular transformation is that the  
11 six-coordinated triangular prism coordination geometry of Cd(II) cation in **1** change to the  
12 seven-coordinated pentagonal bipyramid coordination geometry of Cd(II) cation in **2**, where  
13 one of the oxygen atoms takes on an additional Cd–O5 (coordinated water molecule)  
14 interaction to become (2.463(3) Å, 2.279(2) Å, 2.463(3) Å and 2.279(2) Å for **1** vs. Cd–O =  
15 2.394(1) Å, 2.485(1) Å, 2.320(1) Å and 2.644(1) Å for **2**). This leads to the distances change  
16 of the intermolecular oxygen atom-to-oxygen atom (2.187(1) Å, 3.649(2) Å, 2.187(1) Å and  
17 3.649(2) Å for **1** vs. 2.218(1) Å, 3.325(2) Å, 2.208(3) Å and 4.987(1) Å for **2**); nitrogen  
18 atom-to-nitrogen atom (3.214(2) Å for **1** vs. 3.476(2) Å for **2**) (Fig. 5). Consequently, the  
19 existence of coordinated water molecule led us to explore possible SCSC transformation. The  
20 above structure analysis implies that the transformation between **1** and **2** involves changes of  
21 lattice parameters, bond reformation, and coordination geometry of the Cd(II) site. Note that  
22 in the literature the instance of SCSC from 2D layer to 3D framework interpenetrating  
23 structures has little been established.

## 24 Powder X-ray diffraction (PXRD) and thermogravimetric analysis (TGA) studies

25 PXRD has been used to check the phase purity of the bulky samples in the solid state. As  
26 shown in Fig. S3, the experimental PXRD patterns of complexes **1** and **2** are in good  
27 agreement with the simulated patterns, which indicate the good phase purity of complexes **1**  
28 and **2**. The differences in intensity may be due to the preferred orientation of the crystalline  
29 powder samples.<sup>36,37</sup> To confirm the simultaneous structural transformation with the  
30 breaking/forming of the coordination bonds process, complex **1** is heated to 110 °C, 140 °C,  
31 170 °C, 200 °C and 220 °C then analyzed with PXRD (Fig. 6). Upon heating, the pattern  
32 suddenly changed at 200 °C. The pattern of heating was consistent with the simulated pattern  
33 generated by the crystallographic data of **2**. This **2** was maintained upon cooling to 80 °C, this  
34 process was unsuccessful; therefore, this SCSC conversion is irreversible.<sup>38</sup>  
35 Thermogravimetric experiments were conducted to study the thermal stability of complexes **1**  
36 and **2** (Fig. S4).<sup>39–41</sup> The TGA curve shows that **1** has one weight-loss stage. The weight-loss

1 of 76.26% in the temperature range of 271~319 °C is attributed to the loss of two HIBA  
 2 ligands. The value is close to the calculated value of 77.32%. In the TGA curve of **2**, there are  
 3 two continuous weight-loss steps. The weight loss of 9.52% in the temperature range of  
 4 342~378 °C corresponds to the one coordination water molecule and two and half free water  
 5 molecules which is in accordance with the calculated value of 11.47%. The second  
 6 weight-loss of 68.18% at 411~462 °C is considered as the two HIBA ligands (calcd: 68.45%).

7  
 8 **Fig. 5** The detailed structure change of **1** and **2** structures and the coordination geometry of Cd(II) ions  
 9 involved in this SCSC transformation.

10  
 11 **Fig. 6** Photographs of the crystal transformation from **1** to **2**, and the powder X-ray diffraction patterns in  
 12 the process of crystal transformation.

## 1 **Optical properties of complexes 1 and 2**

2 Fig. 7a shows the UV-visible absorption spectra of the two complexes and N719 in ethanol  
3 solution and the corresponding data are listed in Table 2. Complexes **1** and **2** display strong  
4 absorption bands at 335 nm and 352 nm with weak absorption peaks at 380 nm and 386 nm,  
5 respectively. Compared with the absorption spectrum of N719, the absorption spectra of **1** and  
6 **2** could compensate for that of N719 in the low wavelength region of ultraviolet and  
7 blue-violet. More importantly, the molar extinction coefficients in the blue-violet region are  
8  $41333 \text{ M}^{-1} \text{ cm}^{-1}$  for **1** and  $46643 \text{ M}^{-1} \text{ cm}^{-1}$  for **2**, which are much higher than that of the  
9 ruthenium complex N719.<sup>42,43</sup> Such higher molar extinction coefficients indicate **1** and **2**  
10 possess higher light harvesting ability in this wavelength region compared with N719 and  $\text{I}_3^-$   
11 ( $25,000 \text{ M}^{-1} \text{ cm}^{-1}$ ).<sup>44</sup> To confirm the compensated and suppressed function of **1** and **2**, the  
12 absorption spectra of **1**/N719 and **2**/N719 sensitized  $\text{TiO}_2$  films are recorded and shown in Fig.  
13 7b. The  $\text{TiO}_2$  films co-sensitized by N719 and the prepared complexes led to surprising  
14 results in their absorption spectra in the visible region.<sup>45,46</sup> The two clear absorption bands of  
15 N719 in ethanol solution at 383 and 525 nm are broadened at both sides when it attaches to  
16 the  $\text{TiO}_2$  film, indicating the formation of Herring-bone aggregates by N719 on the  $\text{TiO}_2$   
17 nanocrystal surface. When any one of the prepared complexes is incorporated into the N719  
18 sensitized  $\text{TiO}_2$  film, the intensities of the two characteristic absorption bands increase a lot.  
19 Besides, the two absorption bands at 554 and 367 nm attributed to N719 move to 546 and 372  
20 nm for **1** (552 and 383 nm for **2**), respectively, suggesting that the aggregation degree of N719  
21 on the  $\text{TiO}_2$  film has decreased. The alleviation of aggregates adjusts the arrangement of  
22 N719 molecules toward a more uniform orientation and formed a compact layer with  
23 complexes.<sup>47</sup> Apparently, the increment of the absorption intensity of the  $\text{TiO}_2$  films after  
24 co-sensitization will contribute to their spectral responses as well as the power conversion  
25 efficiency of the DSSCs.

26 The emission spectra of **1** and **2** are illustrated in Fig. 8. All of them exhibit strong  
27 fluorescence in the region of wavelengths 350–750 nm, and it is worth noting that all of the  
28 emission spectra of **1** and **2** overlap with the excitation spectra of N719 inordinately. This  
29 indicates that N719 could synchronously accept the energy from the incident light and the  
30 excited complexes, which will broaden the spectral response of N719 in the region of  
31 350–750 nm.

### 5 Electrochemical properties of complexes 1 and 2

6 Energy-level matching is greatly crucial for co-sensitizer materials used in DSSCs. The  
7 highest occupied molecular orbital (HOMO), lowest unoccupied molecular orbital (LUMO)  
8 energy levels and the excitation transition energy ( $E_{0-0}$ ) can be calculated conveniently by  
9 equations as follows:<sup>48</sup>

$$10 \text{ HOMO (eV)} = -e(E_{\text{onset}}^{\text{ox}} \text{ V} + 4.4\text{V}); \quad \text{LUMO (eV)} = E_{\text{HOMO}} + E_{0-0}$$

11 As estimated from the intersection of the normalized absorption and emission spectra, the  $E_{0-0}$   
12 value is 3.05 eV for 1 and 2.99 for 2. As shown in Fig. S5, from the onset of the ground state  
13 oxidation peak in the cyclic voltammetry (CV), the HOMO value of 1 and 2 are calculated as  
14  $-5.31$  eV and  $-5.22$  eV, respectively. Thus, the LUMO level of 1 and 2 are estimated to be  
15  $-2.26$  eV and  $-2.23$  eV, respectively. For efficient electron injection and regeneration of the  
16 photo-oxidized dye, the LUMO level of a sensitizer should lie above the energy level of the  
17 conduction band (CB) of the TiO<sub>2</sub> semiconductor ( $-4.40$  eV vs. vacuum) and its HOMO

1 energy level should lie below the energy level of the  $\Gamma^-/I_3^-$  redox couple in the presence of  
 2 4-*tert*-butyl pyridine ( $-4.85$  eV vs. vacuum).<sup>49,50</sup> The LUMO levels of the **1** and **2** are higher  
 3 than that of N719 and the conduction band of  $TiO_2$ , which conduce to an enhanced injection  
 4 driving force of electrons compared with alone N719.<sup>51</sup> Therefore, the positive synergistic  
 5 effect of these complexes and N719 improves the electrons injection efficiency from the  
 6 LUMO of dye to the conduction band of  $TiO_2$ . The experimental data are summarized in  
 7 Table 2 and the HOMO and LUMO energy levels of **1** and **2** are shown in Scheme 1. Thus,  
 8 the suitability of **1** and **2** as co-sensitizers in  $TiO_2$  based DSSCs can be considered.

9 **Table 2** Experimental data for spectral and electrochemical properties of complexes **1** and **2**

| Complexes | $\lambda_{abs}(nm)^a$ | $\epsilon(M^{-1}cm^{-1})^a$ | $\lambda_{em}(nm)^{a,b}$ | $E_{0-0}(eV)^c$ | $E_{ox}/V_{vs SCE}^d$ | $E_{HOMO}(eV)$ | $E_{LUMO}(eV)$ |
|-----------|-----------------------|-----------------------------|--------------------------|-----------------|-----------------------|----------------|----------------|
| <b>1</b>  | 380                   | 41333                       | 453                      | 3.05            | 0.91                  | -5.31          | -2.26          |
| <b>2</b>  | 386                   | 46643                       | 467                      | 2.99            | 0.82                  | -5.22          | -2.23          |

 16 calculated for  $TiO_2$

### 17 Photovoltaic properties of DSSCs

18 To prove the accuracy of the above assumption for the complexes as co-sensitizers, **1**/N719  
 19 and **2**/N719 were fabricated with a stepwise co-sensitization procedure by sequentially  
 20 immersing the  $TiO_2$  electrode (with thickness of ca.  $10 \mu m$ ) in separate solution of prepared

1 complexes and N719. For comparison purpose, devices sensitized by individual dye N719  
 2 were also fabricated under the same experimental conditions. As shown in Fig. 9, the  
 3 photocurrent-voltage ( $J$ - $V$ ) characteristic of the DSSCs devices under illumination (AM 1.5 G,  
 4  $100 \text{ mW cm}^{-2}$ ) displayed that the conversion efficiency ( $\eta$ ) value of individually N719  
 5 sensitized device is 6.52% (with  $J_{\text{sc}} = 15.36 \text{ mA cm}^{-2}$ ,  $V_{\text{oc}} = 0.73 \text{ V}$ , and  $FF = 0.58$ ). This low  
 6 performance compared to the previous reports could be due a single thin transparent  $\text{TiO}_2$  film  
 7 used in these devices. The individually **1** and **2** sensitized devices exhibited  $\eta$  value of 1.87%  
 8 (with  $J_{\text{sc}} = 4.66 \text{ mA cm}^{-2}$ ,  $V_{\text{oc}} = 0.65 \text{ V}$ , and  $FF = 0.61$ ) and 1.97% (with  $J_{\text{sc}} = 4.89 \text{ mA cm}^{-2}$ ,  
 9  $V_{\text{oc}} = 0.66 \text{ V}$ , and  $FF = 0.61$ ), respectively. The lower  $\eta$  value for devices sensitized by the  
 10 complexes sensitizers individually is obviously attributed to their narrow adsorption bands.  
 11 However, the cell co-sensitized by **1**/N719 and **2**/N719 exhibited the better overall conversion  
 12 efficiency ( $\eta$ ) of 7.82% (with  $J_{\text{sc}} = 18.13 \text{ mA cm}^{-2}$ ,  $V_{\text{oc}} = 0.74 \text{ V}$ , and  $FF = 0.58$ ) and 8.39%  
 13 (with  $J_{\text{sc}} = 18.40 \text{ mA cm}^{-2}$ ,  $V_{\text{oc}} = 0.75 \text{ V}$ , and  $FF = 0.61$ ), which are 19.94% and 28.68%  
 14 higher than that of cells individually sensitized by N719. The corresponding cells  
 15 performances are summarized in Table 3. According to the results of test, the higher  $\eta$  value of  
 16 co-sensitized solar cell compared with the individually N719 sensitized devices is attributed  
 17 to the enhanced photovoltaic parameters  $J_{\text{sc}}$  and  $V_{\text{oc}}$ .

18  
 19 **Fig. 9**  $J$ - $V$  curves for DSSCs based on co-sensitized photoelectrodes and individual N719, **1**, **2**  
 20 sensitized photoelectrode under irradiation.

21 **Table 3**  $J$ - $V$  performance of DSSCs based on different photoelectrodes

| Photoelectrode                 | $J_{\text{sc}}/\text{mA}/\text{cm}^2$ | $V_{\text{oc}}/\text{V}$ | $FF$ | $\eta/\%$ |
|--------------------------------|---------------------------------------|--------------------------|------|-----------|
| N719/ $\text{TiO}_2$           | 15.36                                 | 0.73                     | 0.58 | 6.52      |
| <b>1</b> / $\text{TiO}_2$      | 4.66                                  | 0.65                     | 0.61 | 1.87      |
| <b>2</b> / $\text{TiO}_2$      | 4.89                                  | 0.66                     | 0.61 | 1.97      |
| <b>1</b> /N719/ $\text{TiO}_2$ | 18.13                                 | 0.74                     | 0.58 | 7.82      |
| <b>2</b> /N719/ $\text{TiO}_2$ | 18.40                                 | 0.75                     | 0.61 | 8.39      |

1 The results mentioned above are also supported by dark current-voltage ( $J$ - $V$ )  
 2 measurements of different devices, which are presented in Fig. 10. It could provide useful  
 3 information regarding the back electron transfer process by making a comparison of dark  
 4 current between the investigated cells. It shows that the dark current is lower for the  
 5 co-sensitized system compared with that of single N719 sensitized DSSC, which is in the  
 6 order of  $2/N719 < 1/N719 < N719$ . The reduction of the dark current demonstrated that **1** and  
 7 **2** successfully suppress the electron back reaction with  $I_3^-$  in the electrolyte by forming a  
 8 compact layer with N719.

9  
 10 **Fig. 10**  $J$ - $V$  curves for DSSCs based on co-sensitized photoelectrodes and N719 sensitized  
 11 photoelectrode in dark.

12 The incident photon-to-current conversion efficiency (IPCE) measurements of different  
 13 devices were conducted to further understand the effect of co-sensitizers with different  
 14 complexes on the photocurrent of DSSCs, and the spectra are collected in Fig. 11, which is  
 15 related by the equation:

$$J_{sc} = \int e\phi_{\text{ph.AM1.5G}}(\lambda)d\lambda$$

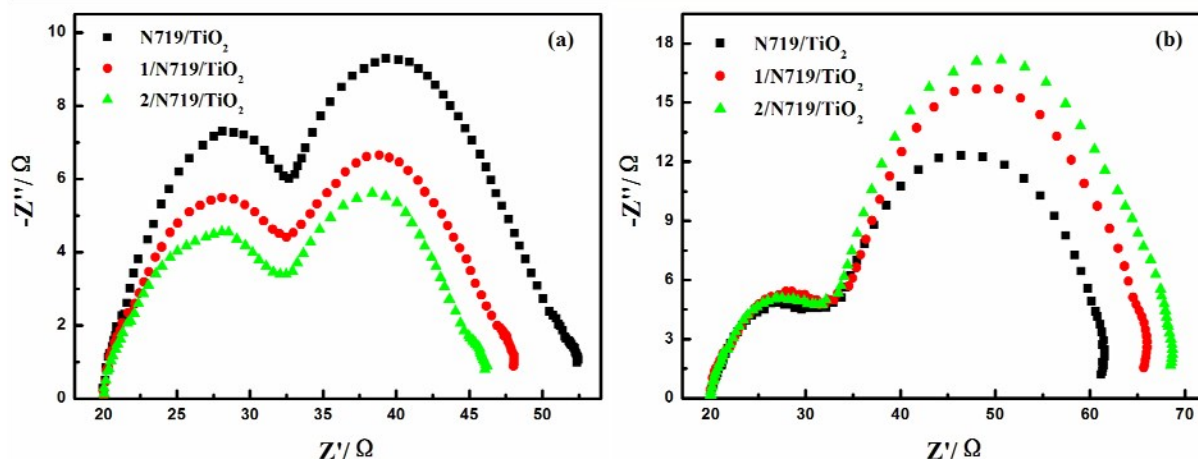

16 where  $e$  is the elementary charge and  $\phi_{\text{ph.AM1.5G}}$  is the photon flux at AM 1.5 G, 100 mW/cm<sup>2</sup>  
 17 irradiation.<sup>52-54</sup> The cell individually sensitized by N719 has a 300–750 nm broad IPCE  
 18 spectrum but in the wavelength range of 340–420 nm the intensity decreases, which is due to  
 19 the competitive light absorption between  $I_3^-$  and N719. When the prepared complex is used as  
 20 co-sensitizer, this decrease is efficiently inhibited as well as the IPCE spectrum is enhanced in  
 21 the whole visible region. This is attributed to the fact that co-sensitizers have attached on the  
 22 TiO<sub>2</sub> surface and contributed to the electron injection into CB of the TiO<sub>2</sub>, which is beneficial  
 23 for light harvesting, electron injection and collection on TiO<sub>2</sub>. Based on the IPCE and the  
 24 absorption spectra, the cell's higher  $J_{sc}$  in the case of co-sensitization is mainly ascribed to  
 25

- 1 better light harvesting in the low wavelength region, where the absorption of N719 is  
 2 compensated and the competitive light absorption of  $I_3^-$  is overcome.

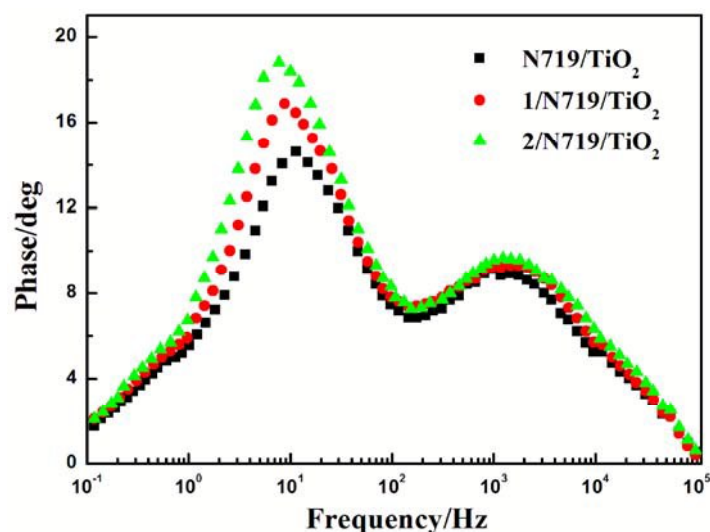

3  
 4 **Fig. 11** The incident photon-to-current conversion efficiency spectra of devices based on single N719  
 5 sensitized and co-sensitized photoanodes.

6 Furthermore, to get the information about the electron transport mechanism in different  
 7 devices, their electrochemical impedance spectra (EIS) were measured under standard AM 1.5  
 8 G solar irradiation by applying a forward bias of  $-0.75V$ .<sup>55,56</sup> Under light illumination, as  
 9 shown in Fig. 12a, the two semicircles located in high and middle frequency regions (left to  
 10 right) are attributed to the electrochemical reaction at the Pt/electrolyte interface and the  
 11 charge transfer at the  $TiO_2$ /dye/electrolyte interface. The radius of the large semicircle located  
 12 in the middle frequency regions in the Nyquist plots decrease after co-sensitization, and the  
 13 values are in sequence for  $2/N719 < 1/N719 < N719$ , which indicates a decrease in the  
 14 electron transfer impedance and an increase in the charge transfer rate at this interface after  
 15 co-sensitization. Above results confirm higher charge transfer rate and lower charge  
 16 recombination rate are beneficial for enhancing the performance of DSSCs. In dark conditions,  
 17 as shown in Fig. 12b, the electrons are injected from the FTO substrate into the  $TiO_2$  and the  
 18 film is charged by electron propagation through the mesoscopic  $TiO_2$  network. Meanwhile, a  
 19 fraction of the injected conduction band electrons are lost by the reduction of  $I_3^-$  ions present  
 20 in the electrolyte. Therefore, we could measure impedance spectra of DSSCs in the dark to  
 21 study the electrons recombination from the conduction band of  $TiO_2$  to  $I_3^-$  ions. The radius of  
 22 the large semicircle located in the middle frequency regions in the Nyquist plot increase after  
 23 co-sensitized with the complexes, and the values are in the order of  $2/N719 > 1/N719 > N719$ ,  
 24 which indicates the retardation of the charge recombination between injected electron and  $I_3^-$   
 25 ions in the electrolyte, with a consequent increase of  $V_{oc}$ .

**Fig. 12** Nyquist plots of EIS for DSSCs based on different photoelectrodes measured under standard AM 1.5 G solar irradiation (a) or in the dark (b) at forward bias  $-0.75$  V.

In an effort to understand the enhancement of the  $V_{oc}$  value in the dye-sensitized solar cells, the electron lifetime ( $\tau_e$ ) in different devices were calculated by fitting the Bode plots of the EIS spectra of different solar cells in dark (Fig. 13), according to the relationship:  $\tau_e = 1/(2\pi f_{max})$ , where  $f_{max}$  is the frequency at the maximum of the curve in the intermediate frequency region in Bode phase plot.<sup>57</sup> The electron lifetime ( $\tau_e$ ) for the devices co-sensitized with **1** and **2** was found to be 18.12 and 20.55 ms, respectively, which are all longer than that of individually N719 sensitized device (13.94 ms). This difference might be expected, since the adsorption of prepared complexes may form a better dye coverage to help to passivate the  $TiO_2$  surface or form an insulating molecular layer composed of prepared complexes and N719 molecules. It will reduce the recombination due to electron back-transfer between  $TiO_2$  and  $I_3^-$ . This retardation of the charge recombination between injected electron and  $I_3^-$  ions in the electrolyte, leads to a consequent increase of  $V_{oc}$ . This appears to be consistent with the larger  $V_{oc}$  values sequence which is in the order of  $2/N719 > 1/N719 > N719$ .

**Fig. 13** Bode plots of EIS for DSSCs based on different photoelectrodes measured in dark conditions.

## 1 **Influence of Structures for DSSCs**

2 Obviously, the strategy of employing the complexes as co-sensitizers to decorate the  
3 interface in a TiO<sub>2</sub> photoanode is an efficient method. It has demonstrated that the highly  
4 porous nature of the complexes increases the dye loading, and owing to its electrical  
5 insulating property the interfacial complex layer suppresses the interfacial charge  
6 recombination. The possible photoanode status after co-sensitization is shown in Scheme  
7 2. Furthermore, when the structures of the complexes are taken into account, it is found  
8 that there is a relationship between crystal structure and DSSCs performance. First, for  
9 complexes **1** and **2**, they adsorbed on Nano TiO<sub>2</sub> thin film surface through carboxyl which  
10 has various coordination modes with metal ions, such as bidentate-chelate,  
11 bidentate-monatomic, chelate-monatomic, *etc.* Although carboxyl has coordinated to the  
12 Cd<sup>2+</sup> ion in complexes, Ti<sup>4+</sup> ion may also be coordinated with carboxyl due to the  
13 existence of lone pair electrons in carboxylate oxygen atom which could combine with  
14 Ti<sup>4+</sup> ion to form Ti-O coordination bond, and further adsorbed on the TiO<sub>2</sub> film. Second,  
15 the nitrogen atoms of organic ligands were expected to adsorb at the Lewis acid sites of  
16 the TiO<sub>2</sub> surface. Third, the structure of **1** and **2** contain channel, which can be assembled  
17 together to form high surface area arrays for photon collection.<sup>58</sup> Besides the dyes tightly  
18 anchored onto the TiO<sub>2</sub> surface ensure the efficiency of photocurrent output, the additional  
19 dyes adsorbed onto complexes can contribute to the improvement of conversion  
20 efficiency. Compared with 2D lay structure (complex **1**), the presence of 3D framework  
21 (complex **2**) may tighten the whole skeleton, thus resulting in much weaker vibrations,  
22 which is beneficial to electronic energy transfer. Therefore, the performance of the  
23 co-sensitized cell is in the order of **2**/N719 > **1**/N719.<sup>59</sup>

**Scheme 2.** Possible photoanode status after co-sensitization.

## 1 Conclusion

2 In conclusion, we have reported an interesting a 2D two-fold interpenetrating square lattice  
3 layer **1** transformation to a 3D four-fold interpenetrating diamond framework **2** by thermal  
4 treatment of the reaction system. Such SCSC transformation process involving the change  
5 coordination geometry of central metal and breakage/formation of chemical bonds is quite  
6 rare. Meanwhile, the two high dimensional interpenetrating complexes display outstanding  
7 photovoltaic performance. **1** or **2** as co-sensitizer has a significant effect on the performance  
8 of DSSCs, it could overcome the deficiency of N719 absorption in the region of ultraviolet  
9 and blue-violet, offset competitive visible light absorption of  $I_3^-$  and reducing charge  
10 recombination of injected electron. The co-sensitized device exhibits enhanced performance,  
11 and all of them are higher than that of single N719 sensitized solar cells. The special  
12 performance for high dimensional interpenetrating complexes as potential light harvesting and  
13 energy transferring materials in DSSCs inspires us to further explore the higher photoelectric  
14 conversion efficiency in the future.

## 15 Acknowledgments
