non-fullerene acceptors for organic photovoltaics,<sup>1</sup> 2D materials for photodetectors<sup>2</sup> and metal halide perovskites for a broad range of devices, such as light-emitting diodes or solar cells.<sup>3</sup> With remarkable advances in their synthesis, processing and integration into functional devices, the performances of these optoelectronic devices are reaching highly competitive levels in comparison to conventional technologies. This makes the future of such novel materials and their application in optoelectronics on an industrial scale more promising

than ever. However, to realise their full potential on a commercial level, not only do the desired function and performance need to be achieved, but also their stability needs to be enhanced in order to reach the necessary lifetimes set by the different applications.

The study of material and device stability naturally takes a secondary role in the development of novel materials. Researchers focus on showcasing the desired performance first, in order to provide proof-of-concept devices that demonstrate the material's potential for

and Best Paper Award 2016 of the Industrial Research and Consultancy Center, IIT Bombay. His current research interest involves solution-processible inorganic and organic semiconductors, the understanding of their charge transport and photo-physics and transfer of that knowledge to the design of high performance optoelectronic and piezotronic devices.

Prof. Dinesh Kabra is working at the Department of Physics at IIT Bombay, Mumbai – India. He is in charge of emerging PV technologies at the National Center for Photovoltaic Research and Education (NCPRE) at IITB and is also an associated faculty member at the Center for Semiconductors for Innovations and Technologies (SEMIX). Prof. Kabra is the recipient of the DST Solar Challenge Award 2022, Early Research Achiever Award 2015

application. Nowadays, several classes of materials have already reached a certain level of maturity and the demonstration of superior performance is no longer the only goal of research. More and more attention is now diverted to understanding the fundamental processes that govern material and device degradation and the development of suitable mitigation strategies.<sup>4,5</sup> The themed collection “Stability of Optoelectronic Materials and Devices” aims to highlight some of the best reports dedicated to the topic and motivate further research into this challenging and exciting field of materials chemistry.

From a chemical point of view, understanding how the molecular structure of a molecule impacts on its stability is highly important. This is highlighted in the excellent report by K. J. Thorley *et al.*, who investigated a series of different derivatives of anthradithiophenes to identify the factors that influence their photostability (<https://doi.org/10.1039/D2TC02922G>). The authors demonstrate that substituents at certain molecular positions tend to increase photostability, with the optimal position depending on the type of substituent. Based on these insights the authors suggest a range of future design principles that can lead either to more stable materials for optoelectronics, or alternatively more reactive materials for application as sensors.

The processing of materials during device fabrication may also impact on the stability of the optoelectronic device.

The work by C. Zhao *et al.* illustrates this by comparing standard spin-coating of a binary polymer blend to a sequential deposition of the same polymers during the fabrication of an organic solar cell (<https://doi.org/10.1039/D2TC04142A>). The researchers demonstrate that sequential processing not only results in improved photovoltaic performance, but also enhanced device stability. These improvements are associated with the differences in the vertical distribution of the two polymers achieved by the different processing methods.

An alternative approach to increasing device stability is through the engineering of its structure to introduce additional components that mitigate the deterioration of performance by suppressing the degradation pathway. This approach was adopted by S. Yoon *et al.* who introduced various CeO<sub>2-x</sub> nanostructures into an organic solar cell structure to act as free radical scavengers (<https://doi.org/10.1039/D2TC04152A>). The authors demonstrated that single-crystalline hollow CeO<sub>2-x</sub> nanorods were very effective as hydroxyl radical scavengers, resulting in an enhanced device stability of the solar cell upon continuous illumination.

These selected examples illustrate the broad range of research fields that are involved in the complicated task of improving the stability of optoelectronic materials and devices. These range from chemistry to materials science to device physics and engineering and include a

plethora of challenging research questions. We hope that this themed collection inspires readers to extend their own research to include the study of material and device stability and the development of approaches for their enhancement.
