We report an expeditious catalytic asymmetric approach to clavine alkaloids via a key Heck cyclization. This reaction sets the formation of vicinal stereocenters with excellent diastereoselectivity. Utilizing the aforementioned strategy, the formal total synthesis of cycloclavine (**1**) has been achieved via another key late-stage esteraminolysis of **6**.

Clavine alkaloids (**1** and **2**; Fig. 1) are a subclass of the ergot family of indole-containing alkaloids produced by several members of the *Clavicipitaceae* and *Trichocomaceae* families of filamentous fungi.<sup>1,2</sup> They have also been identified in plants of the families *Convolvulaceae*, *Poaceae* and *Polygalaceae*.<sup>3</sup> Ergot alkaloids (**1**–**4**; Fig. 1) primarily target serotonin (5-HT) receptors<sup>4a</sup> and  $\alpha$ -adrenergic and dopamine receptors. Reportedly, some natural or semisynthetic ergoline derivatives are used as

drugs, such as pergolide (**2d**) used as an anti-prolactin and anti-Parkinson's disease drug.<sup>4,5</sup>

Therefore, significant progress has been made in the identification and characterization of genes responsible for the biosynthesis of clavine alkaloids (Fig. 1).<sup>6</sup> Structurally, clavine alkaloids can exist in pentacyclic [such as cycloclavine (**1**)] and tetracyclic [such as festuclavine (**2a**–**c**)] forms.<sup>4b</sup> Lysergic acid (**3a**) (and its derivatives such as ergometrine **3b** and ergopeptam alkaloids **4a**–**b**) differs from clavine alkaloids **2a**–**c** only in the oxidation state [see, **3a**].<sup>7a,b</sup>

Cycloclavine (**1**) was isolated from the seeds of the African morning glory shrub *Ipomoea hildebrandtii*, and later from a species of filamentous fungus, *Aspergillus japonicus*.<sup>8a,b</sup> Although smaller in size, structurally cycloclavine (**1**) poses a formidable challenge because of its complex architecture with a pyrrolidine ring linked with a strained cyclopropane ring with three contiguous stereocenters, out of which two are vicinal all-carbon quaternary stereocenters.<sup>9</sup> Despite the encouraging medicinal value of select clavine congeners, a comprehensive biological evaluation for the majority of these naturally occurring alkaloids has yet to be undertaken. From 2008 till 2016, only racemic syntheses of cycloclavine (**1**) have been reported, out of which three total syntheses<sup>10–12</sup> and two formal total syntheses<sup>13,14</sup> are reported. Interestingly, two consecutive coupling reactions such as selective alkylation of a dienolate and an intramolecular Heck reaction are utilized by Opatz and Netz for a racemic formal synthesis of cycloclavine (**1**).<sup>14</sup>

Recently, the first catalytic enantioselective total synthesis of unnatural (–)-cycloclavine (*ent*-**1**) has been achieved by Wipf and McCabe<sup>15a</sup> via Rh-catalyzed enantioselective cyclopropanation (up to 74% ee) of an unsubstituted allene to access a methylene-cyclopropane derivative. Very recently, Cao and co-workers have reported an elegant formal total synthesis of naturally occurring (+)-cycloclavine (**1**)<sup>15b</sup> while our manuscript was under preparation. This synthesis features a Zn-mediated asymmetrical nucleophilic addition of *N*-tert-butanefulfinimine, an intramolecular esteraminolysis reaction followed by isomerization of an exocyclic double bond and a late-stage intramolecular Heck coupling reaction.<sup>15b</sup>

Scheme 1 Retrosynthetic analysis of cycloclavine (1).

In this context, a unified strategy for the synthesis of **1** and **2** in enantioenriched form would present opportunities to provide access to significant quantities of the natural products and related analogues.

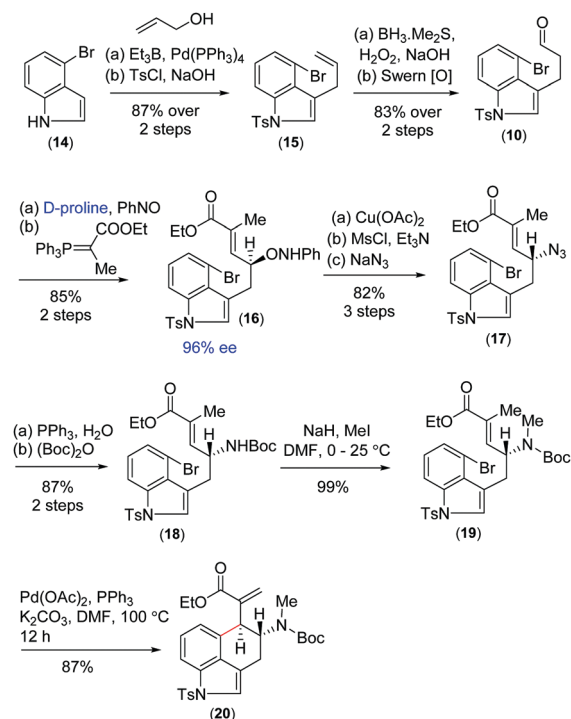

Retrosynthetically, we envisioned that cycloclavine (**1**) can be synthesized from an advanced enantiopure intermediate  $\alpha,\beta$ -unsaturated amide **5** (Scheme 1) *via* isomerization followed by reduction of the amide functionality and cyclopropanation.<sup>10</sup> Compound **5** can be accessed from  $\alpha,\beta$ -unsaturated ester **6**, which could in fact be the advanced intermediate for clavine alkaloids **2a–d** sharing vicinal stereocenters (Fig. 1). We reasoned that ester **6** has the potential to afford two different tetracyclic intermediates such as **5** and **13** (Scheme 2). An ester-aminolysis of **6** can provide access to **5**, on the other hand **6** can also afford ester **13** following a 5-*endo-trig* cyclization (Scheme 2). We argued that as the secondary amine (HOMO) and C=O  $\pi^*$  (LUMO) are in proper alignment (see the orbital representation in **11**), an ester-aminolysis of **6** would be facile to afford tetracyclic amide **5**. However, a 5-*endo-trig* cyclization of **6** would not be possible because of bad alignment of the secondary amine (HOMO) and C=C  $\pi^*$  (LUMO) (see the orbital representation of intermediates **12a** and **12b**).

Scheme 2 An ester-aminolysis versus 5-*endo-trig* cyclization of  $\alpha,\beta$ -unsaturated ester **6**.

Further, we thought that  $\alpha,\beta$ -unsaturated ester **6** with an *exo*-double bond can be synthesized *via* a key intramolecular Heck cyclization of allylamine **7** (Scheme 1). Enantioenriched allylic amine **7** can be synthesized from allylic alcohol **8** *via* Mitsunobu type inversion using an azide nucleophile followed by synthetic manipulations. Non-racemic allyl alcohol **8** can be accessed from aldehyde **10** *via* a D-proline catalysed  $\alpha$ -aminoxylation reaction with nitrosobenzene through the intermediate aldehyde **9** (Scheme 1). Importantly, since both enantiomers of proline are commercially available, one can synthesize both antipodes of allylic alcohols, *i.e.* **8** and *ent*-**8**.

On the basis of previous studies on the proline catalysed  $\alpha$ -aminoxylation reaction of aliphatic aldehydes with nitrosobenzene,<sup>16</sup> we decided to investigate the potential of this process in the catalytic asymmetric total synthesis of clavine alkaloids (Fig. 1). Towards this direction, we synthesized 3-allyl-4-bromoindole **15** from the Pd(0)-catalyzed reaction of 4-bromoindole **14** with allyl alcohol in the presence of triethylborane using Tamaru's report.<sup>17</sup> This was then reacted with borane followed by oxidation with H<sub>2</sub>O<sub>2</sub> in the presence of NaOH to afford a primary alcohol, which was then oxidized to obtain aldehyde **10** under Swern oxidation (Scheme 3). Having aldehyde **10** in hand, we then conducted a catalytic enantioselective  $\alpha$ -aminoxylation reaction with nitrosobenzene in the presence of 10 mol% D-proline (Scheme 3). This reaction afforded an  $\alpha$ -aminoxylated aldehyde, which was immediately reacted with a stabilized Wittig reagent prepared from 2-bromo ethylpropionate to afford compound *E*-ester **16** as the sole isomer in 85% yield over 2 steps with 96% enantioselectivity.<sup>18</sup>

With compound **16** in hand, our effort was thereafter to elaborate to allylic amine **19** for key Heck cyclization

Scheme 3 Asymmetric synthesis of key  $\alpha,\beta$ -unsaturated ester **20**.

(Scheme 3). Towards this, N–O bond cleavage was performed with anhydrous  $\text{Cu}(\text{OAc})_2$ ,<sup>19,20</sup> followed by mesylation and azide formation, affording **17** in 82% yield over 3 steps. The azide functionality was reduced under Staudinger conditions, followed by Boc-protection leading to intermediate **18** in 87% yield over 2 steps. The latter was *N*-methylated using methyl iodide to afford allyl amine **19** (Scheme 3). The intramolecular Heck cyclization of **19** was performed with 5 mol%  $\text{Pd}(\text{OAc})_2$  and 10 mol%  $\text{PPh}_3$ . Gratifyingly, this reaction afforded a single diastereomer of **20** in 87% yield (Scheme 3).<sup>21</sup>

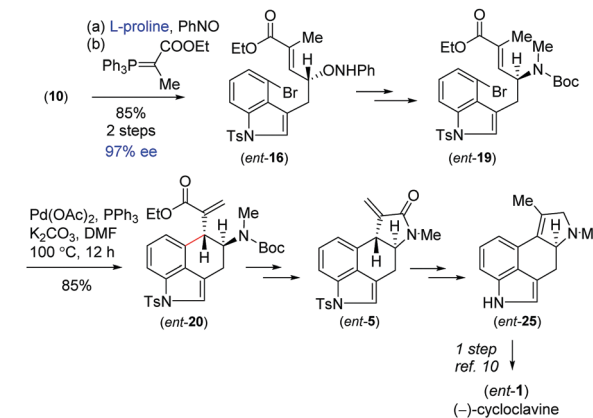

We urged that the Heck cyclization of **19** can proceed through the intermediate  $\text{Pd}(\text{II})$ -species **21a** (Scheme 4). However, in order to minimize the steric clash, **21a** could immediately form **21b** via a C–C bond rotation. The formation of the tetra-substituted  $\alpha,\beta$ -unsaturated ester **22** from this intermediate is not possible since  $\text{Pd}(\text{II})$  and  $\beta$ -hydride are *anti*-position to each other (Scheme 4). At this situation, a  $\beta$ -hydride transfer from an adjacent methyl group in **21c** could afford **20** having vicinal stereogenic centers (Scheme 4).

Further, compound **20** was elaborated under a key cyclization in order to get the tetracyclic core of cycloclavine (**1**). Towards this, we deprotected the Boc group in the presence of trifluoroacetic acid at 25 °C to afford **6**, which under refluxing toluene afforded the ester-aminolysis product **5** with an exocyclic double bond in 88% isolated yield over 2 steps (Scheme 5).<sup>22</sup> To our delight, no trace of the 5-*endo-trig* cyclization (aza-Michael reaction) product was observed, as confirmed from <sup>1</sup>H-NMR analysis of the crude reaction mixture.

With the enantioenriched tetracyclic **5** in hand, we then isomerized to  $\gamma$ -lactam using cesium carbonate in THF to afford **23** in 94% yield (Scheme 5).<sup>23</sup> The latter was reduced using  $\text{LiAlH}_4$  in the presence of  $\text{AlCl}_3$  to furnish the electron-rich tetrasubstituted double bonded product **24** in 89% yield.<sup>24</sup> Further, in order to access the antipode of **25**, we performed the catalytic enantioselective  $\alpha$ -aminoxylation reaction of **10** with nitrosobenzene in the presence of 10 mol% *L*-proline, which afforded the product *ent*-**16** in 97% ee after a Wittig reaction (Scheme 6). This enantioenriched material was elaborated to *ent*-**25** via a similar reaction sequence as shown in

Scheme 5 Asymmetric synthesis of (+)-cycloclavine (**1**).

Scheme 6 Asymmetric synthesis of (–)-cycloclavine (*ent*-**1**).

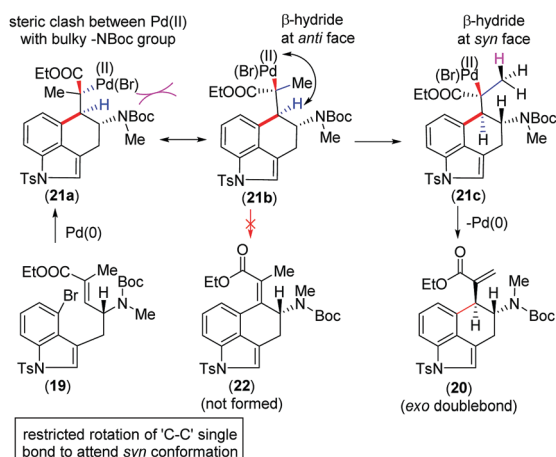

Schemes 3 and 5. As the total synthesis of cycloclavine (**1**) from **25** is known, our effort culminated in the formal total synthesis of this alkaloid.

In summary, the catalytic enantioselective formal total synthesis of both antipodes of cycloclavine (**1**) has been achieved via a late stage ester-aminolysis of an  $\alpha,\beta$ -unsaturated ester intermediate **6**. The vicinal stereocenters of this advanced intermediate were established following an intramolecular Heck cyclization of an enantioenriched  $\alpha,\beta$ -unsaturated ester having allylamine **19**. Since both enantiomers of proline are inexpensive and commercially available, our strategy offers an expeditious approach to either enantiomer of cycloclavine (**1**). Further efforts for a rational extension of the strategy to other congeners of clavine alkaloids are underway and will be reported in due course.<sup>25</sup>
